## Anti-arrhythmic Action of Bretylium

THE anti-arrhythmic action of guanethidine which was found to prevent a type of clinical paroxysmal ventricular tachycardia<sup>1</sup> and prevented experimental atrial fibrillation<sup>2</sup> suggested that other agents which interfere with the release of catecholamines might exhibit similar effectiveness.

The procedure used to test this possibility was derived from a method which I developed earlier. In this, after control observations which eliminate animals that occasionally exhibit susceptibility to acetylcholine-induced atrial fibrillation, insulin and glucose are administered. This causes a drop in plasma potassium concentration to a low stable level which occurs in about thirty minutes and remains relatively stationary for about ninety minutes. During this time, dogs are highly susceptible to atrial arrhythmias. This is called the 'susceptible period'.

During the susceptible period, at 15-20-min intervals, the dogs were administered acetylcholine intravenously in doses starting with 0.3 mg/kg. Previous studies have shown that with an unprotected dog such a dose will provoke atrial fibrillation almost routinely (98 per cent) and the fibrillatory dose is usually 0.1 mg/kg or less<sup>3</sup>.

In the initial investigations, the test drug was administered immediately after the test subject had exhibited episodes of acetylcholine-induced atrial fibrillation at least twice at 0.3 mg/kg or less. After administration of the test drug, a latent period of 10 min or more was permitted. Then the preparation was challenged as before with incremental doses of acetylcholine to the maximum dose of 0.5 mg/kg. In later experiments, longer latent periods (up to 18 h) were allowed before challenge. The challenge period, 30-120 min after insulin-glucose administration, was rigidly maintained regardless of the time of administration of the test drug.

Atrial fibrillation at any dose was deemed 'lack of protection', but 'protection' means that the test drug protected at the highest dose (0.5 mg/kg) and all lower doses. The highest dose was administered three or more

Table 1. EFFICACY OF BRETILIUM TO PROTECT AGAINST EXPERIMENTALLY INDUCED ATRIAL FIBRILLATION (Some groups have been combined when the data obtained indicated close agreement of the parameter under observation)

¶ ACh dose 0.4.

times and a percentage was calculated from the protected challenges divided by the total number of challenges. These are the figures shown in columns 6 and 7 of Table 1.

In addition to the specific tests to determine anti-fibrillatory activity of bretylium, four other related determinations were made: (1) An attempt was made to determine the latent period before activity of the drug after intravenous and subcutaneous administration. (2) The period of maximum effectiveness of the drug was sought. (3) The duration of the drug action was ascertained for various dose levels. (4) An attempt was made to determine a dose-effect relationship at the previously found time of maximum effectiveness. To do this, dogs which were not protected at low doses were allowed rest periods of a week, then they were administered a higher dose of bretylium and retested. The dosage range for this series was 2.5-30.0 mg/kg.

In all, 108 experiments were performed, involving 20 dogs. The pertinent experiments are presented in Table 1. All the dogs used exhibited susceptibility to atrial fibrillation in separate control experiments before and after experimental runs with bretylium.

Bretylium exhibited an anti-fibrillatory effect in a reasonably constant fashion which was dose-dependent when the drug was administered subcutaneously. Intravenous administration of bretylium led to inconsistent results unless the drug was infused over 10-15 min. Rapid renal excretion is assumed to be the factor concerned with this decrease in efficacy. Both rapid and prolonged injections are presented together in Table 1.

An examination of the results obtained yields the following conclusions: (1) Doses of 2.5 mg/kg or less were almost ineffective. (2) Some dogs were protected at all doses above 2.5 mg/kg. (3) A period of about 4 h was necessary for maximum effectiveness. (4) The effect of the drug was greatly diminished at 8 h. (5) Nearly all the dogs were protected at 30.0 mg/kg or less (18 of 20). (6) At the time of maximum effectiveness (4-5 h), with the highest dose (30.0 mg/kg), only two dogs were not fully protected (series x). (7) No anti-arrhythmic effect was found at 18 h except with the highest dose (30.0 mg/kg) (series z).

It became evident during this work that the results followed an approximate linear log dose-response relationship, for with each increase of the dose of bretylium, more of the dogs were protected. The number of observations for each point is inadequate to define the curve specifically, but the hypothesis that the maximum dose (30.0 mg/kg) would be completely protective was tested. With experiments at the highest dose (30.0 mg/kg), three dogs which

were unprotected at lower doses were retested. With this dose of bretylium, one dog was totally protected and two others were partially protected—that is, protected against 0.4 mg/kg but not against 0.5 mg/kg acetylcholine. The value of continuing with greater dosage of bretylium was dubious.

Previous reports which relate this anti-arrhythmic activity have not been found. Boura and Green<sup>4</sup> have reported local anaesthetic action which may be operant here. However, it is surprising that a 4-h delay is necessary before activity is demonstrated and intravenous injections have very low immediate efficacy, since one would expect local anaesthetic action to have less latency.

The diminished action after 12 h may suggest that the action herein reported may not be related to prevention of catecholamine release since such a mechanism has been shown to be maximum at about 20 h<sup>5</sup>. The similarity of pharmacological action for bretylium and previously reported for guanethidine implies a related mechanism.

I thank Burroughs Wellcome and Co. for a supply of bretylium. This work was supported by the Central Ohio Heart Association.

## HAEMATOLOGY

### Blood Preservatives for the Glutathione Stability Test

WHEN red cells deficient in glucose-6-phosphate (G-6-PD) are incubated with acetylphenylhydrazine under standardized conditions, there is a marked drop in concentration of reduced glutathione (GSH). Under the same conditions, the GSH of normal cells is relatively unaffected<sup>1</sup>. This procedure, the glutathione stability test, has been widely used in the diagnosis of G-6-PD deficiency<sup>2</sup>.

Recently, Davies and Gower<sup>3</sup> reported that ACD (acid-citrate-dextrose), used as a blood preservative for carrying out the GSH stability test, was unsatisfactory unless its pH was adjusted to 7.6. This finding was quite surprising

Table 1

Day of storage	pH 5.0 system		pH 7.6 system	
	Initial GSH (mg/100 ml. RBC)	After 2 h incubation with APH (mg/100 ml. RBC)	Initial GSH (mg/100 ml. RBC)	After 2 h incubation with APH (mg/100 ml. RBC)
0	57.0	56.31	51.1	39.5
6	50.23	44.70	55.16	43.96
13	46.45	47.0	53.71	52.76
20	53.24	41.08	51.55	30.23
27	48.29	41.94	54.37	16.82
35	45.33	36.00	45.39	13.82

to us, since both Szeinberg *et al.*<sup>4</sup> and McGovern *et al.*<sup>5</sup> had reported that the glutathione stability test gave satisfactory results for up to 4 weeks when blood was stored in ordinary ACD solution, and their results were recently confirmed by Palek and Volek<sup>6</sup>. Many other investigators have used ACD as a preservative solution for the purpose of this test. We have, therefore, compared the GSH stability of normal blood preserved in ACD, National Institutes of Health formula B, at the usual pH 5.0, and as recommended by Davies and Gower<sup>3</sup> at pH 7.6. The GSH stability test was carried out as originally reported<sup>1</sup>, except that the DTNB method<sup>7</sup> was used for the determination of glutathione.

Several samples of blood were examined. The results of a typical experiment are summarized in Table 1. When blood was preserved in ordinary ACD solution glutathione stability was essentially unaltered for approximately 4 weeks. When blood was stored in ACD solution the pH of which had been adjusted to 7.6, GSH was abnormally unstable initially, and markedly so after 3 weeks.

Careful examination of the studies of Davies and Gower clarifies the reason for the discrepancy between their findings and those of others. It is apparent that Davies and Gower have carried out the glutathione stability test in a manner very unlike that originally reported<sup>1</sup> and used by other investigators. They have pre-incubated their blood samples at 37° C for 24 h prior to carrying out the glutathione stability test. Studies carried out in this laboratory have recently shown that ACD solution, with pH values of 5.0 are very poor preservatives of red cell ATP (adenosine triphosphate) at 37° C, when compared with solutions of pH 7.6 (ref. 8). Adenosine triphosphate is required for the utilization of glucose by red cells. It might, therefore, not be surprising that some red cells would manifest better GSH stability after prolonged incubation at 37° C in such a preservative solution than in the ordinary ACD solution. It must be emphasized, however, that the glutathione stability test is not carried out by pre-incubating blood at 37° C for 24 h. Only a 2-h incubation is involved. As shown in Table 1, when the test is carried out in the conventional manner, ACD solution pH 5.0 is clearly superior to ACD solution pH 7.6. The latter solution cannot, therefore, be recommended as a preservative for the glutathione stability test.

## PATHOLOGY

## 'Yellow Fat' in the Wild Rabbit

DURING investigations into the population dynamics of the European wild rabbit (*Oryctolagus cuniculus* L.) on the island of Skokholm, Pembrokeshire, an abnormal condition of adipose tissue was observed. The condition is apparently unknown in rabbits elsewhere, except on the adjacent island of Skomer, and is hitherto undescribed.

During the severe winter of 1962-63 about half the Skokholm population of approximately 6,000 rabbits became emaciated and died. Healthy, dead and dying rabbits were collected and examined in February and March 1963. Necropsy showed that about half of these had no fat deposits, but most of the remainder had abundant fat of a yellow-brown colour around the kidneys. It extended along the para-vertebral areas into the pelvis to enclose the bladder ventrally. Normal fat was observed in very few animals. In animals where the change was slight, dark brown or yellow pin-point spots could be seen; in late winter and spring, both yellow and brown patches were commonly seen in the same animal. The 'yellow fat' is characteristically marbled or mottled in appearance, varies in colour from orange-yellow to dark brown, and unlike normal fat is hard and firm in the live animal; the surface of severely mottled fat is usually smooth, but it may occasionally be rough and uneven. The incidence of moderate and severe mottling is greatest during periods of reduced food quality, and, in females, during pregnancy and lactation. The condition has been seen in animals as young as six weeks.

Histological examination of the fat showed adipose tissue cells of variable size, some small ones bordered by giant cells and small clusters of histiocytes. The fat was divided into small lobules by strands of fibrous tissue, which contained occasional clusters of granules of a brown pigment. Staining by Nile-blue sulphate, sudan dyes, perchloric acid naphthoquinone<sup>1</sup> and the O.T.A.N. methods<sup>2</sup> demonstrated the presence of abundant neutral fat, together with free fatty acids and some phospholipid in the region of the giant cells. Cholesterol was not demonstrated, though birefringence was seen where fatty acids occurred. Much of the fatty material present was not soluble in lipid solvents; extraction of carbowax sections with chloroform-methanol (2:1) failed to remove any appreciable quantity of sudanophilic material, and sections of tissue embedded in paraffin wax also showed abundant material stainable with the sudan dyes.

The brown pigment was not acid-fast, but was positive to Schmorl's reaction. It was not autofluorescent. Prolonged oxidation of unsaturated fats can produce such a pigment. The condition is similar to lipogranulomatous conditions such as sclerema neonatorum, which occurs in man; similar conditions have been described in mink<sup>3</sup>, cat<sup>4</sup>, pig<sup>5</sup> and rat<sup>6</sup>. In these cases, a high intake of polyunsaturated fat (for example, cod liver oil) in the presence of a relative deficiency of vitamin E has been implicated. It is likely that the rabbits we describe, living on a small island inhabited by numerous sea-birds and with a sparse growth of grass, are ingesting some such fish oils. In the absence of vitamin E, unsaturated fats can give rise to unstable peroxides, and thus to the brown oxidation products which are described here. These can stimulate an inflammatory reaction in the tissues where they occur.

Seito *et al.*<sup>7</sup> stated that 'yellow fat' in pigs was more fluid than normal fat. We have not found this to be so in the rabbit, probably because the fat is interspersed with fibrous tissue and resinous oxidation products. The 'yellow fat' does not seem able to act as a reserve food store, as does normal fat. The rabbits, dying of starvation, still possess appreciable perirenal adipose tissue, though of this altered nature.

### High Antihæmophilic Factor In Multiple Myeloma

An investigation of antihæmophilic activity in 18 patients with multiple myeloma showed a high antihæmophilic factor (AHF) in 10 cases. The elevated AHF values were not related to hyperglobulinaemia or any other factor which could be determined.

AHF assay was performed by the method of Bergna<sup>1</sup>. Assays on 52 normal plasmas ranged from 50 to 200 per cent of the group mean. Assays were performed on 18 patients with multiple myeloma in various stages of the disease. The blood was drawn at 10.00 a.m. and at bed rest except for one ambulant patient. Symptoms of fever and pain and medications were noted. No patients were studied directly after transportation to the hospital, and none had acute fractures.

The AHF assays of the 18 patients were examined in relation to the age and sex of the patient; total serum protein and albumin and globulin fractions; serum and urine electrophoresis with quantitation of serum proteins by electrophoresis using the Beckman/Spinco 'Analytrol'; immuno-electrophoresis<sup>2</sup> using anti-gamma 2 and anti-gamma<sub>1</sub> A sera; content of plasma cells in particle smears of aspirated marrow; therapies employed in treatment; and the clinical state of the patient.

Twelve patients had elevated AHF values. Nine were over 300 per cent of the normal group mean, the highest value recorded being 630 per cent. Eleven of these 12 cases with elevated AHF had hyperglobulinaemia, and one had a normal serum globulin level with gamma globulin in the urine. The patient with the highest AHF assay was untreated and had normal total protein and a normal serum globulin fraction by chemical determination, but had an elevated beta fraction by electrophoresis, and gamma<sub>1</sub> A by immuno-electrophoresis. Of the remaining six cases, five had normal AHF levels and marked hyperglobulinaemia. One patient, untreated, aged 74, was lowest in AHF (30 and 60 per cent) and had a very high gamma of 77.2 per cent with a total protein of 10.1 g per cent.

The plasma and serum of one patient, whose plasma contained 390 per cent AHF, were studied in the thromboplastin generation test<sup>3</sup>. His plasma, diluted with 7 parts of hæmophilic plasma, produced a normal TGT, while normal plasma diluted with 3 parts of the same hæmophilic plasma give an abnormal TGT. The patient's serum showed no thromboplastic effect. Cohn 'Fraction I' prepared from this patient assayed at 85 per cent of the original plasma AHF. Later, 160 ml. of the same patient's plasma containing 2.92 units of AHF in 1 ml. (1 unit = 1 ml. of normal plasma assaying 100 per cent AHF activity) was fractionated by the method of Cohn<sup>4</sup>. 'Fraction I', dissolved in 15.5 ml., had an assay of 22.7 units per ml., representing 75 per cent of the original activity.

Pitney and Elliott<sup>5</sup> demonstrated that Australian Aborigines, who have hyperglobulinaemia, have a higher plasma AHF than white Australians. They also found elevations of AHF in white Australians who had hyperglobulinaemia associated with lymphosarcoma, autoimmune disease, hepatic cirrhosis, nephrosis and multiple myelomatosis. They thought the rise in AHF might be related to the increased globulin production. Pitney *et al.*<sup>6</sup> studied AHF in normal families and concluded that there was no relation to sex, but there was an increase with age. They found no relation between concentrations of AHF and plasma proteins, particularly gamma globulin, in their normal individuals. Amundsen *et al.*<sup>7</sup> reported elevated AHF levels in patients with carcinoma. Ingram<sup>8</sup> found an increase in AHF following infusion of adrenaline, and Iatrides<sup>9</sup> demonstrated elevated AHF after exercise. Increase in AHF after trauma and childbirth has been shown by Davidson and Tomlinson<sup>10</sup>. Increase in AHF in pregnancy has been reported by Strauss and Diamond<sup>11</sup>.

In the present study there was no consistent correlation of the AHF activity with age, sex, therapy, hyperglobulinaemia, type of abnormal globulin (gamma 2 or gamma<sub>1</sub> A), degree of plasma cell hyperplasia in the bone marrow, or clinical state of the patient. No patients had any recognised thrombotic complications.

The site of origin of AHF is not known. One wonders if the abnormal protein production by the plasma cells in multiple myeloma could include AHF or AHF activator<sup>12</sup> in some cases.

The high AHF values in patients with multiple myeloma are a good source of this factor for experimental purposes. The highly concentrated AHF from such plasma is being used in an attempt to produce anti-AHF antibody in the experimental animal.

This investigation was supported in part by grant TIAM 5108, U.S. Public Health Service.

### Gel-filtration of Isotopically labelled Ferritin from HeLa Cells

HeLa human cancer cells have been shown to produce ferritin when grown in the presence of iron<sup>1</sup>. HeLa ferritin is electrophoretically heterogeneous; its properties have been compared with those of ferritin isolated from other cells grown *in vitro* and from human and animal tissues<sup>2</sup>. On DEAE chromatography of homogenates of HeLa cells grown in the presence of FeSO<sub>4</sub> (<sup>57</sup>Fe), the distribution of the radioactivity was practically the same as the distribution of ultra-violet-absorbing components in the case of purified horse ferritin; the assignment of the activity to ferritin has been confirmed by paper electrophoresis<sup>3</sup>. The use of radio-iron in such experiments results in great sensitivity and specificity. We now report the behaviour of HeLa ferritin on gel-filtration.

HeLa cells were grown in bottles, and the well-developed monolayers incubated for 24 h with  $10 \mu\text{g FeSO}_4$  and  $0.3\text{--}0.5 \mu\text{Ci } ^{55}\text{Fe}$  per ml., as described previously<sup>3</sup>. The cells were collected and homogenized, and the microsomal and the 105,000g supernatant fractions were obtained as before<sup>3</sup>. The microsomal pellet and the supernatant were diluted with buffer to give solutions with an absorbancy of 30–50 at 210 m $\mu$ , and 0.3–0.5 ml. of these solutions was placed on the column. Usually columns  $55 \times 1$  cm were used; they were loaded to a height of 50 cm with 'Sephadex G-200' (Pharmacia, Uppsala), pretreated with 0.15 M NaCl + 0.02 M phosphate buffer. However, satisfactory separations were also obtained with shorter columns ( $35 \times 1$ , and even  $20 \times 1$  cm). Care has to be taken not to use too concentrated a solution of whole homogenate or of the microsomal fraction, or the flow may be too slow. Elutions were carried out with 0.15 M NaCl + 0.02 M phosphate buffer (pH 7.3–7.4) at a flow rate of 10 min per 1.5-ml. fraction. The absorbancy at 210 and 260 m $\mu$  was measured against a blank of the eluting solution after suitable dilution of the fractions<sup>4</sup>. The activity was determined with a well-type scintillation gamma-spectrometer.

Typical 'fritograms' of the HeLa whole cell homogenate show three peaks (Fig. 1). The pattern is general for cell homogenates; similar fritograms have been obtained with human fibroblasts and liver cells (unpublished results). With the microsomal fraction one symmetrical sharp peak is found (Fig. 2). This fraction is almost free from components of molecular weight below 200,000. The great absorbancy at 260 m $\mu$  indicates a high content of nucleic acids, and the variation in the ratio of the absorptions at 210 and at 260 m $\mu$  between different parts of the peak

Fig. 1. Gel-filtration of whole cell homogenate. 1 ml solution (absorbancy 30 at 210 m $\mu$ ) was placed on the column ( $35 \times 1$  cm) loaded to a height of 30 cm. The flow rate was 1 fraction (1 ml.)/5 min. Absorbancy at 210 m $\mu$ , O, at 260 m $\mu$ , ■.

Fig. 2. Gel filtration of microsomal fraction. The column dimensions were  $55 \times 1$  cm and the flow rate 1 fraction (1.5 ml.)/10 min. Absorbancy at 210 m $\mu$ , O, at 260 m $\mu$ , ■; radioactivity, Δ.

Fig. 3. Gel-filtration of the 105,000g supernatant. Column and signs as in Fig. 2.

suggests the presence of molecular species with unequal nucleic acid contents.

A different pattern is obtained with the 105,000g supernatant (Fig. 3). Small amounts of material passing the column without entry into the gel are noted. Most of the material of the 105,000g supernatant emerges in the second peak. This is asymmetrical; presumably it could be resolved further at slower flow rates. The third peak consists of low-molecular components with high absorption at 260 m $\mu$ ; it is missing from cell homogenates dialysed before gel-filtration. To judge from the 210/260 ratio, the first and second peaks, although macromolecular, are chemically different from the microsomal peak. Values of the ratio between 12 and 25 were obtained for the 105,000g supernatant fractions, and only between 2.8 and 3.1 for the corresponding microsomal fractions.

The distribution of the radio-iron in the microsomes as well as in the 105,000g supernatant is interesting. In both fritograms a fairly sharp peak appears that is distinct from the microsomal peak (Fig. 2) and also from the first peak of the 105,000g supernatant (Fig. 3). The appearance of the radioactivity in the range of the material excluded from the gel is consistent with the known values of the molecular weight of ferritin. Apoferritin has a molecular weight of 465,000 (ref. 5) and that of ferritin itself is up to 747,000, depending on the iron content<sup>6,7</sup>. The displacement of the radioactivity peaks as compared with the absorption peaks suggests the possibility of differentiation of macromolecules with weights greater than 200,000, the approximate exclusion limit from 'Sephadex G-200'. The discrimination by 'Sephadex' columns of molecules heavier than 200,000 is also reflected by the differences of the 210/260 ratio between different parts of both the microsomal peak and the first peak of the 105,000g supernatant.

Purified horse spleen ferritin<sup>8</sup> behaved on gel-filtration on 'Sephadex G-200' like the radioactive component of homogenates of HeLa and of fibroblasts grown *in vitro*<sup>8</sup>. When  $^{55}\text{Fe}$ -labelled homogenate of fibroblasts was mixed with horse ferritin and run through the column, the position of the radioactivity peak was almost the same as that of the absorbancy peak. It thus appears that the molecular size of ferritin of the cells grown *in vitro* is similar to that of ferritin in animal tissues.

The results obtained demonstrate the suitability of gel-filtration for the analysis of cell homogenates. Macromolecular components can rapidly be separated from low-molecular substances. The method is also well suited to the separation of the microsomal fraction from smaller macromolecules and for the differentiation of components of the 105,000g supernatant. The effectiveness of the separation is well illustrated by the sharpness of the ferritin peak in the fritogram, as measured radiochemically.

## IMMUNOLOGY

### Specifically Increased Graft-versus-Host Reactivity of Thymus Cells from Immunized Mice

It has recently been shown that thymus cells from immunized mice are capable of transferring immune reactivity. Sub-lethally irradiated recipient mice exhibit recall tetanus antitoxin production after they have been injected with thymus cells from mice immunized with tetanus toxoid<sup>1</sup>. Similarly, thymus cells from mice immunized with bovine serum albumin are capable of transferring antibody formation capacity when injected into non-irradiated recipients<sup>2</sup>. The work recorded here was undertaken to determine whether thymus cells from mice immunized to  $F_1$  hybrid histocompatibility antigens would exhibit specifically increased graft-versus-host immunological reactivity after injection into  $F_1$  hybrid mice of the immunizing strain. We will show that immunization does specifically increase the graft-versus-host reactivity of thymus cells, and that the relative increase in reactivity is similar to that observed with injection of spleen cell populations from similarly immunized animals.

$A$ -strain mice 45 days of age were divided into three groups. One group of mice received an immunizing injection of 50 million ( $A \times O3H$ ) $F_1$  hybrid spleen cells intraperitoneally. Another group received an immunizing injection of 50 million ( $A \times O57BL/1$ ) $F_1$  hybrid spleen cells intraperitoneally, and a third group was not immunized. Foreign pure strain cells were not used for immunization for two reasons. First, injected lymphoid cells have been shown to enter the thymus<sup>3</sup>, and therefore pure strain cells might persist there long enough to be able to give a graft-versus-host reaction of their own in our assay system. Secondly, injected pure strain cells might exert a graft-versus-host reaction against the injected  $A$ -strain mice, thus interfering with the immunological apparatus of the injected mice<sup>4</sup>. Between 10 and 21 days after immunization, mice were killed under ether anaesthesia, their thymuses removed, and thymus cell suspensions prepared in lactate-Ringer's solution, using a loose-fitting Potter-Elvehjem glass homogenizer. The immunological capacity of these thymus cell suspensions was evaluated by the graft-versus-host assay of Simonsen *et al.*<sup>5</sup>. This assay measures the degree of spleen enlargement induced in young  $F_1$  hybrid recipients of lymphoid cell suspensions from one of the parental strains. Litters of 6-8-day-old ( $A \times O3H$ ) and ( $A \times O57BL/1$ ) $F_1$  hybrid mice were used for all assays. Each suspension of thymus cells was assayed by injecting 60 million thymus cells intraperitoneally into ( $A \times O3H$ ) $F_1$  hybrid recipients, and 10 million thymus cells intraperitoneally into ( $A \times O57BL/1$ ) $F_1$  hybrid recipients. Negative controls consisted of non-injected littermates of the injected  $F_1$  hybrid recipients.

Eight days after cell suspension administration the hybrids were killed, their body and spleen weights determined, and the relative spleen weight (mg spleen/10 g body-wt.) calculated. Finally, in each litter the 'spleen index' was determined by dividing the mean relative spleen weight of the mice receiving thymus cell suspensions by the mean relative spleen weight of the non-injected control mice. In an attempt to quantitate the increase of reactivity of thymus and spleen cells resulting from immunization, we have also compared the immunological reactivity of spleen and thymus cells from immunized donors with the reactivity of spleen and thymus cells from non-immunized donors. The graft-versus-host assays of spleen and thymus cells from normal donors were performed and evaluated exactly as already described here, and the data obtained represent a portion of another study which is as yet unpublished.

It is apparent that thymus cells derived from  $A$ -strain mice immunized with ( $A \times O3H$ ) $F_1$  hybrid cells show increased graft-versus-host reactivity in ( $A \times O3H$ ) $F_1$  hybrid recipients (Table 1). Similarly, thymus cells from  $A$ -strain mice immunized with ( $A \times O57BL/1$ ) $F_1$  hybrid cells show increased reactivity in ( $A \times O57BL/1$ ) $F_1$  hybrid recipients. The specificity of this increased reactivity is shown by the failure of thymus cells from immunized donors to exhibit increased reactivity in the test strain to which they were not immunized. The comparison between cell suspensions from immune and non-immune donors is shown in Table 2. It can be seen that the reactivity of 10 million thymus cells from immunized mice does not differ significantly from the reactivity of 20 million thymus cells from non-immune donors, and similarly the reactivity of 1 million spleen cells from immunized mice is approximately equivalent to the reactivity of 2 million spleen cells from non-immune donors.

It can be concluded that the thymus participates in the process of immunization against histocompatibility antigens at least to the extent of containing cells which exhibit increased specific immune reactivity. Our results are similar to those of Fiore-Donati *et al.*<sup>6</sup>, who also showed increased graft-versus-host reactivity after immunization. However, these authors did not show the specificity of the reaction, whereas our experiments demonstrate conclusively that the increased immunological reactivity is specific for the immunizing antigen. There are

Table 1. SPECIFICITY OF INCREASED IMMUNOLOGICAL REACTIVITY EXHIBITED BY THYMOCYTES FROM IMMUNIZED  $A$ -STRAIN MICE

Donor	No. donors assayed	Strain of recipient animal	No. thymus cells injected ( $\times 10^6$ )	Mean spleen index* obtained $\pm S.E.$
Normal $A$	7	( $A \times O3H$ ) $F_1$	60	1.19 $\pm$ 0.05
$A$ immune to ( $A \times O3H$ ) $F_1$	8	( $A \times O3H$ ) $F_1$	60	1.58 $\pm$ 0.07
$A$ immune to ( $A \times O57BL/1$ ) $F_1$	7	( $A \times O3H$ ) $F_1$	60	1.14 $\pm$ 0.04
Normal $A$	8	( $A \times O57BL/1$ ) $F_1$	10	1.17 $\pm$ 0.04
$A$ immune to ( $A \times O57BL/1$ ) $F_1$	12	( $A \times O57BL/1$ ) $F_1$	10	1.51 $\pm$ 0.08
$A$ immune to ( $A \times O3H$ ) $F_1$	7	( $A \times O57BL/1$ ) $F_1$	10	1.26 $\pm$ 0.07

\* Spleen indexes were calculated by dividing the relative spleen weight (mg spleen/10 g body-wt.) of the experimental group by the relative spleen weight of the negative control group (non-injected litter-mates).

Table 2. IMMUNOLOGICAL REACTIVITY OF THYMUS AND SPLEEN CELLS FROM NORMAL AND IMMUNE  $A$ -STRAIN MICE

Donor	No. donors assayed	Type of cells injected	No. cells injected ( $\times 10^6$ )	Mean spleen index* in ( $A \times O57BL/1$ ) $F_1$ hybrids $\pm S.E.$
Normal $A$	9	Spleen	2	1.83 $\pm$ 0.11
$A$ immune to ( $A \times O57BL/1$ ) $F_1$	7	Spleen	1	1.29 $\pm$ 0.14
Normal $A$	9	Thymus	1	1.91 $\pm$ 0.13
$A$ immune to ( $A \times O57BL/1$ ) $F_1$	11	Thymus	20	1.65 $\pm$ 0.12
Normal $A$	7	Thymus	10	1.20 $\pm$ 0.08
$A$ immune to ( $A \times O57BL/1$ ) $F_1$	12	Thymus	10	1.51 $\pm$ 0.08

\* Spleen indexes were calculated by dividing the relative spleen weight (mg spleen/10 g body-wt.) of the experimental group by the relative spleen weight of the negative control group (non-injected litter-mates).

at least two hypotheses which can account for the presence of sensitized cells in the thymus of the immunized animals. On one hand, the cells exhibiting increased reactivity may have migrated to the thymus after being sensitized in the peripheral lymphoid organs. Alternatively, the immunizing cells or antigens may have entered the thymus and sensitized the thymus cells directly. Both hypotheses are consistent with the findings from parabiosis<sup>7</sup> and spleen cell injection<sup>8</sup> experiments showing that lymphoid cells can enter the thymus. These experiments have also shown that the relative increase of immunological reactivity after immunization is approximately as great for thymus cells as for spleen cells. This finding suggests that the immunologically responsive cells of the thymus participate in the development of immunity as represented by the graft-versus-host reaction to approximately the same extent as do the responsive cells of the spleen.

## Distribution of Agglutinating Antibodies to *Listeria monocytogenes* among Vertebrates

INVESTIGATIONS of the host-parasite relationship of *Listeria monocytogenes* to man and to several species of domestic ungulates have revealed that serum antibodies reactive with the bacterium may be found in a high percentage of apparently normal individuals<sup>1</sup>. The proper interpretation of these immunological reactions has been a persisting question in serology, particularly since the species concerned are subject to clinical listeriosis. Do the antibodies demonstrate a high level of inapparent infection by a ubiquitous organism wherein few of the attacked individuals experience the clinical disease, or do they arise from antigenic stimuli other than *L. monocytogenes* and manifest cross-reactivity because heterogenetic antigen systems are involved?

Indirect evidence in answer to the question was sought by testing the sera of a number of vertebrates for agglutinating antibodies. The study involved reptiles and fish as

well as birds and mammals. Most of the serum samples were collected at the San Diego Zoo, California; others were obtained from animals in their natural habitat. The sera were tested in a somatic agglutinating system starting at the 1:25 dilution<sup>2</sup>. Antigen was prepared from a strain of *L. monocytogenes* belonging to serotype 4b. Three or more thermostable antigenic determinants occur on the organism, thus reactivity of antibodies from different sera are not necessarily directed against the same determinant group. Reactions were recorded by visual estimation as follows: 4+ = 100 per cent of cells agglutinated, 3+ = 75 per cent of cells agglutinated, 2+ = 50 per cent of cells agglutinated, 1+ = 25 per cent of cells agglutinated, and 0 = no cells agglutinated.

As shown in Table 1, only 15 of 118 mammalian sera tested failed to demonstrate some agglutinating activity. The ruminants were distinguished among the mammals by the greater percentage showing reactions and by the generally high titres. Likewise, among the birds it was found that a high percentage had antibodies. Eighty-four per cent of the birds reacted, although the titres tended to be somewhat lower than those obtained from mammals. Sera from 11 fish caught in the Pacific Ocean were tested and 7 contained demonstrable antibodies. The reactions were all obtained from bonita (*Sarda macleoti*), although the group included 1 barracuda and 1 kelp bass. Titres were low, but the presence of antibodies to *L. monocytogenes* in this environment was of special interest. Of the 31 reptiles tested, 2 were lizards and the rest were various species of snakes. As a group of vertebrates, these were the least reactive, since antibody was detected in only 35 per cent. Titres were low except in a few notable examples such as a copperhead snake (*Agkistrodon contortrix latrocinus*), a blotched water snake (*Natrix erythrogaster transversa*), and a monitor lizard (*Varanus exanthematicus albigularis*) which had titres of 1:200. Antibody was detected in 9 of the 17 species of reptiles tested.

The results suggest that sera can be expected to contain antibodies reactive with *L. monocytogenes* even though they are not stimulated by that organism. So far as is known, the ocean may be considered a *Listeria*-free environment, and yet antibodies were detected in both fish and mammals collected from the ocean. Seven of the 9 bonita and 2 of 3 sea-lions reacted in this series. Suggestions that *L. monocytogenes* shares 1 or more heterogenetic antigens with other micro-organisms seems logical, and in the instances cited here it is likely that some marine forms of microbial life have antigenic patterns related to those of *Listeria*. The concept of heterogenetic antigens is likewise strengthened by the presence of antibodies in terrestrial reptiles. It is conceivable that these species could encounter the bacterium by means such as ingestion of infected rodents, but the organism is not known to infect cold-blooded vertebrates, and it is not likely that the presence of antibodies in such hosts can be explained as *Listeria* infections.

The possibility must be considered that certain species might have antibodies which were not stimulated by antigens encountered in the environment. These could be called 'normal antibodies' which might relate to blood group systems or other cellular constituents of the host and have a genetic basis. This can be suspected in situations where a high percentage of individuals of one species react while those of a related species, in a similar environment, do not. This may apply among the reptiles,

Table 1. AGGLUTINATING ANTIBODY TITRES FOR *Listeria monocytogenes* AMONG VERTEBRATES

	Total tested	Zero at 1:25	1+ at 1:25	2+ at 1:25 or greater	2+ at 1:50 or greater	2+ at 1:100 or greater	2+ at 1:200 or greater	2+ at 1:400 or greater	2+ at 1:800 or greater
Ruminant mammals (25 species)	85	9 (11%)	11 (13%)	65 (76%)	61 (72%)	56 (66%)	34 (40%)	18 (21%)	2 (2%)
Non-ruminant mammals (31 species)	31	0 (0%)	8 (26%)	17 (55%)	12 (39%)	9 (29%)	5 (16%)	1 (3%)	1 (3%)
Birds (39 species)	67	9 (13%)	13 (20%)	35 (52%)	33 (49%)	23 (34%)	16 (24%)	9 (13%)	3 (5%)
Salt-water fish (3 species)	11	4 (36%)	2 (18%)	5 (45%)	4 (36%)	2 (18%)	0	0	0
Terrestrial reptiles (17 species)	31	20 (64%)	3 (10%)	8 (26%)	5 (16%)	3 (10%)	3 (10%)	0	0

for example, all the activity being recorded among 9 species, while 8 others, representing 45 per cent of the specimens, showed no reactions.

The prevalence of *Listeria* antibodies among ruminant mammals at the San Diego Zoo requires special consideration. Among the domestic animals, ruminants are most frequently associated with clinical listeriosis. It is therefore tempting to assume that much of the antibody activity encountered here was due to contact with *L. monocytogenes*. However, the authorities at the San Diego Zoo were not aware of any disease problem caused by this organism. The possibility that soil may serve as a habitat for the bacterium has been considered by some investigators<sup>1</sup>. Accordingly, soil samples were collected in nine enclosures at the Zoo where animals had high *Listeria* titres, but no isolations of the organism were made. It is likely that the ruminant animals in the Zoo were in an environment free of *L. monocytogenes* and that the high titres of antibody activity in their sera arose from other causes. Certain organisms peculiar to the ruminant digestive tract might well have antigens in common with *Listeria*, and this may be responsible for these confusing serological results. Neter<sup>4</sup> has reported that *L. monocytogenes* contains the so-called 'Rantz antigen', which has been described as a substance common to several Gram-positive bacteria<sup>5</sup>. This may well be a facet of the problem, but it would appear to be only a part of the explanation, since sera absorbed with various organisms containing 'Rantz antigen' are still reactive with *Listeria* cells.

This note is not to suggest that immune antibodies to *L. monocytogenes* do not occur. Rather, a definition of the problem of serodiagnosis in listeriosis requires that means be found to achieve recognition of those antibodies which arise from contact with antigens of *L. monocytogenes* against a frequent background of cross-reacting antigen-antibody systems.

This investigation was supported in part by research grant AI-1080 from the National Institutes of Health, U.S. Public Health Service, and by a grant-in-aid from the Zoological Society of San Diego.

### Opsonic Requirements for Bacterial Phagocytosis

THAT specific antibody is required for the uptake of most, if not all, bacteria by phagocytic cells has been accepted since the early work on opsonins by Almroth Wright and Douglas. In recent years evidence has accumulated that complement may also be involved since partial removal of complement in a variety of phagocytic systems reduces the rate and amount of uptake<sup>1,2</sup>. The fragments of 7S  $\gamma$ -globulin which can be obtained by enzymatic digestion of antibody are reported to be unable to fix complement in their combination with antigen<sup>3</sup>, and recently Miescher *et al.*<sup>4</sup> have found that such fragments possess little or no activity in an *in vivo* opsonic system. Using a highly sensitive intraperitoneal test in mice we have confirmed that pepsin or pepsin-digest fragments of rabbit 7S antibody are only capable of opsonizing *S. adelaide* when used at a concentration one thousand times greater than the minimum effective dose of the original 7S  $\gamma$ -globulin. Quantitatively similar results with fragment I have recently been obtained by Shands and Suter<sup>5</sup>.

Fragments labelled with iodine-131 were found to combine with the bacterial surface in a manner quantitatively similar to the 7S  $\gamma$ -globulin. This suggests to us that complement-binding on the bacterial surface may be mandatory for phagocytosis to occur.

As a result of this conclusion we have attempted to construct a model whereby complement could be fixed at the bacterial surface in the absence of specific antibody, in order to see if this is the prime requirement for opsonization. The idea was to take normal human  $\gamma$ -globulin, previously adsorbed with *S. adelaide* to remove all specific antibody against the organism. This could then be aggregated by heating to 63° C for 15 min and purified according to the method of Christian<sup>6</sup>, to yield a fairly homogeneous and highly anti-complementary aggregate with a molecular size of approximately 1 million. Similar material has been shown by Laliker *et al.*<sup>7</sup> to adsorb strongly on to the surface of red cells, and there seemed a good possibility that it would attach similarly to bacterial cells and fix complement close to the bacterial surface in an analogous way to specific antibody. The question then arises whether these coated bacteria could be phagocytosed.

We prepared aggregated human  $\gamma$ -globulin in this way, and after labelling with iodine-131 the uptake of this aggregate by 10<sup>7</sup> *S. adelaide* was followed over a range of concentrations of 10  $\mu$ g–2 mg/ml. At all levels approximately 5 per cent of the proffered aggregate was adsorbed to the bacteria and could not be removed by repeated washing with saline. Incorporation of the aggregate alone or when adsorbed to bacteria, into a standard rabbit anti-sheep cell haemolysin complement titration using 6 O'H50 units of guinea-pig complement, showed that approximately 5  $\mu$ g of the aggregate could fix 1 O'H50 unit of guinea-pig complement. Phagocytosis tests were then carried out as follows: 10<sup>7</sup> *S. adelaide* were incubated for 10 min with amounts of aggregated  $\gamma$ -globulin ranging from 10  $\mu$ g to 10 mg/ml, and washed once in saline by centrifuging. The washed suspension was then diluted 1:50 in saline, and 0.1 ml. of this, containing approximately 10<sup>4</sup> organisms, was injected intraperitoneally into each of ten normal mice. At timed intervals thereafter the mice were killed, the surviving organisms recovered by washing out the peritoneum and viable counts made on agar<sup>8</sup>. In a parallel control experiment 1  $\mu$ g of 7S  $\gamma$ -globulin from *S. adelaide* rabbit antiserum was added to the 10<sup>7</sup> organisms before washing and diluting.

Coating with aggregated  $\gamma$ -globulin was completely ineffective and at the end of 90 min most of the injected organisms were recovered from the peritoneum, in sharp contrast to the control with specific antibody where only 0.1 per cent of the organisms were recoverable after this time.

It seemed possible that the aggregated  $\gamma$ -globulin might be inactive due to elution *in vivo*. We have shown that this is not so by following the effect of injecting aggregate-treated bacteria into mice previously immunized against the human  $\gamma$ -globulin. In this case there was rapid phagocytosis and killing presumably due to specific combination between the aggregated globulin on the bacterial surface and specific antibody in the presence of mouse complement *in vivo* (Fig. 1).

We deduce from these findings that, if the opsonic function of antibody requires the participation of complement, this function cannot be imitated merely by attaching complement near to the bacterial surface. Any satisfactory explanation of the mechanism of opsonization must then encompass two points. First, the specific attachment of complement by antigen-antibody complexes, and secondly, the fact that very few molecules of antibody may suffice to opsonize each bacterium. Approximately ten molecules of 19S antibody per bacterium will successfully opsonize *S. adelaide*<sup>9</sup>. This amount of antibody cannot occupy more than 0.1 per cent of the bacterial surface. The original conception of Almroth Wright of a layer of opsonizing protein around the bacteria which he likened

Fig. 1. *In vivo* opsonization of *S. adelaide* coated with aggregated human  $\gamma$ -globulin in normal mice (upper curve) and in mice previously immunized against human  $\gamma$ -globulin (lower curve). The logarithm of the percentage of injected micro-organisms recovered from the mouse peritoneum is plotted as a function of time.

to "buttering a bitter pill" is obviously inadequate. A possible explanation which must now be considered is one which involves production of a chemotactic or activating mediator released by the antigen-antibody combination with complement. Evidence for the existence of such a factor has been provided by Boyden<sup>3</sup> and by Shands and Suter<sup>4</sup>.

## RADIOBIOLOGY

### Geographical Variation in the Total Body Burden of Caesium-137 in Japanese People as assessed by Blood Analysis

IN view of the complexity in the collection of muscle tissues from autopsies throughout the country to assess the total body burden of caesium-137 in Japanese people, an attempt was made to assess it by the analysis of whole blood<sup>1</sup>. This method presents the problem of the relation between the concentration of caesium-137 in blood and the total body burden; when an equilibrium condition is not attained between the total body and diet or blood.

Since the transition rate of caesium-137 from food to blood is considered to be much more rapid than that from blood to the total body, a change in the diet level will be

followed quickly by a change in blood. Therefore, when the level of caesium-137 in the diet is increasing, the factor relating the total body burden to blood concentration will be smaller than when it is decreasing.

This difficulty can be overcome by making parallel determinations on control human subjects of both blood and the total body levels. Such determinations have been made continuously since November 1963 on several members of the staff of this Institute, the main purpose being to determine the long-term variation in the factor relating blood and the total body levels<sup>1,2</sup>.

At the end of July 1964, five samples each of citrated whole blood (from males only) were collected from nine blood banks throughout the country. Each sample, 200 ml. in volume, was ashed after the addition of caesium carrier and its caesium-137 content was determined by a radiochemical method. This method comprises radiochemical separation by a combined ammonium molybdo-phosphate-dipicrylamine-chloroplatinic method and low-background  $\beta$ -counting in 4 $\pi$ -geometry, the chemical yield being a little less than 90 per cent on average, the counting efficiency 69 per cent and the background counting rate less than 1 c.p.m.<sup>3</sup>. This made measuring time less than one hour of the sample activity within a standard error of 10 per cent. The concentration of caesium-137 thus obtained in whole blood was corrected for the content of anti-coagulant. The result shown in Table 1 was averaged for each district and one standard deviation of the mean is also indicated.

The determination on laboratory personnel (males) of blood and the total body levels was made on July 21, 1964, the latter measurement being done at the National Institute of Radiological Sciences by Mr. T. Inuma, and the relation between the levels was found (Table 2).

Salo *et al.* measured the levels of caesium-137 in Finnish Lapps in May 1962, and tried to obtain the correlation between the body burden and the concentration in blood<sup>4</sup>. However, the correlation should be shown between the body burden per unit body-weight and the concentration in blood, because the body burden is a function of the body-weight while the concentration in blood is not. The mean body-weight of the laboratory personnel shown in Table 2 is 56 kg, and this by chance coincides with the average body-weight of Japanese men. Therefore, in this particular case, correction for the body weight was neglected in the assessment of body burden in Japanese. The factor relating the body burden (mc.) to blood concentration (pc./kg blood) was calculated to be 0.44, and this was multiplied by the local mean value of blood concentration shown in the last column of Table 1 to obtain the body burden (Fig. 1).

The figure shows a significant variation between localities, higher body burdens in districts in the north and near

the Japan Sea, lower in districts in the south and near the Pacific. This pattern is very similar to that known for the fall-out deposition rate, and radioactivities in some crops. In Table 1 are shown the levels of caesium-137 in polished rice (crop in autumn 1963) and liquid milk<sup>1</sup> (average for the period spring 1963–spring 1964). Rice was taken because it is one of the main contributors of caesium-137 in Japanese diet, while milk was taken because it may represent locally consumed foodstuffs such as fresh leafy vegetables. The range of geographical variation in blood level is, however, smaller than those in foodstuffs. This may reflect an effect of distribution and consumption of foodstuffs throughout the country as well as the complexity of diet composition.

Measurements have conveniently been made of the total body burden of caesium-137 by using whole body counters. However, when the whole body counter is not available or quite limited in use for the assessment of population mean levels of caesium-137, blood analysis seems to be a promising substitution. The collection of human muscle tissues cannot always be carried out easily and the specimens from autopsies of hospitalized people is subjected to criticism because a bias may be introduced in the assessment for healthy live people. The analysis of muscle tissues obtained from a hospital in Tokyo indicated total body burdens of 10.3, 9.5, 10.3 and 8.4 nCi in April, May, June and July 1964, respectively<sup>2</sup>. The average body burdens of the laboratory personnel in this Institute were measured by a whole body counter as 12.3, 13.0, 14.5 and 14.9, respectively in the same month, given above. The result may indicate a negative bias of 30 per cent on the average when the assessment is based on the analysis of muscles of hospital origin.

### Reversal of some Effects of Gamma-irradiation by the Ethyl Ester of Gibberellic Acid

THREE experiments concern the effect of gamma irradiation in retarding the sprouting of potato tubers and the ripening of tomato fruits.

**Potatoes:** Potatoes (variety 'Up-to-date') were received in the laboratory about 2 weeks after lifting and stored at room temperature (23°–35° C; relative humidity, 70–95 per cent). After being stored for 2½ months, potatoes that were free from sprouts were packaged individually in perforated polyethylene bags. Half of them were irradiated with 12.6 krad of cobalt-60 gamma rays at the rate of 2.1 krad/min. One day after irradiation, half the irradiated and the same number of control tubers were dipped in a solution (150 p.p.m.) of ethyl ester of gibberellic acid (GA) for 25 min. The remaining tubers, irradiated and control, were dipped in distilled water for the same period. The tubers were afterwards dried, re-packaged in perforated polyethylene bags and stored at 11°–12° C (relative humidity (R.H.) 85–90 per cent).

The relevant results are presented in Tables 1–3 and Fig. 1. All the irradiated, gibberellic acid-treated potatoes had sprouted after 25 days of storage; thereafter, the sprouts began to wither. No sprouting occurred in irradiated tubers treated with distilled water. Similar results were obtained by me in an experiment of a different design and conducted at a different temperature<sup>1</sup>. Gibberellic acid also hastened the sprouting of control tubers (Table 1). After 25 days of storage, the fresh weight loss was as follows: (i) Control, GA-treated—2.5 per cent, (ii) control, distilled water-dipped—1.9 per cent, (iii) irradiated, GA-treated—2.2 per cent, and irradiated, distilled water-dipped, 1.4 per cent. Treatment with gibberellic acid caused an increase in the number of buds growing per tuber as well as the number of buds growing on the stem and half of each tuber in irradiated as well as control lots (Table 2). None of the tubers decayed within 25 days of storage.

Fig. 1. Effects of gamma-irradiation and gibberellic acid treatment on potato tubers, photographed after 45 days of storage. (a) irradiated, treated with gibberellic acid, (b) irradiated, dipped in distilled water, (c) control, treated with gibberellic acid, (d) control, dipped in distilled water.

Table 1. NO. POTATOES SPROUTED OUT OF 40 IN EVERY TREATMENT

Storage period (days)	Control		Irradiated	
	GA	Distilled water	GA	Distilled water
5	27	22	12	nil
10	30	24	20	nil
15	24	27	27	nil
20	26	30	28	nil
25	27	31	40	nil

Table 2. SPROUTING AFTER 25 DAYS OF STORAGE

	Control		Irradiated	
	GA	Distilled water	GA	Distilled water
(1) No. of buds growing per tuber*	5.0	3.7	4.8	No sprouting
(2) No. of buds growing on stem-end half per tuber*	0.7	0.4	0.6	No sprouting

\* Means of 40 measurements.

Table 3. FRESH WEIGHT LOSS AND SPROUTING AFTER 45 DAYS OF STORAGE IN CONTROL SERIES

	GA	Distilled water
(1) Percentage cumulative fresh weight loss in potatoes*	5.1	3.8
(2) Length (cm) of longest sprout in a tuber†	2.8	1.9
(3) Length (cm) of longest internode in all the sprouts in a tuber†	1.6	0.9
(4) No. of nodes in the longest sprout in a tuber†	3.2	4.8

\* Determinations were made on samples of 5 tubers.

† Means of 40 measurements.

In control potatoes, treatment with gibberellic acid resulted in an increase in loss of fresh weight, an increase in the length of the sprout, an increase in the internodal length of the sprout and a decrease in the number of nodes in the sprout, after 45 days of storage (Table 3). Fig. 1 shows 4 potatoes, belonging to the 4 treatments, as photographed after 45 days of storage.

**Tomatoes:** Tomatoes (variety 'Marglobe') were picked in the green stage and stored at room temperature (24°–33° C, R.H. 70–80 per cent). After 5 days of storage, fruits that were still green were selected and packaged individually in perforated polyethylene bags. Half of them were irradiated with 12.6 kreds of gamma rays at the rate of 2.1 kreds/min. Three and a half hours after irradiation, half the irradiated and the same number of control fruits were dipped in a solution (150 p.p.m.) of ethyl ester of gibberellic acid for 25 min. Simultaneously, the remaining fruits from each of the irradiated and the control lots were dipped in distilled water for the same period. All fruits were afterwards dried, re-packaged in perforated polyethylene bags and stored at 11°–12° C (R.H. 85–90 per cent).

The results obtained are recorded in Tables 4 and 5. Treatment with gibberellic acid hastened the rate of ripening both in irradiated and control tomatoes (Table 4). After 25 days of storage, the fresh weight loss was as follows: (i) control, GA-treated—2.0 per cent; (ii) control, distilled water-dipped—1.5 per cent; (iii) irradiated, GA-treated—2.3 per cent; (iv) irradiated, distilled water-dipped—1.3 per cent.

Table 4. NUMBERS OF GREEN TOMATOES (OUT OF 40 IN EACH TREATMENT GROUP)

Storage period (days)	Control		Irradiated	
	GA	Distilled water	GA	Distilled water
5	30	26	22	40
10	31	27	23	34
15	11	14	8	23
20	8	10	6	13
25	nil	nil	nil	nil

Table 5. NUMBERS OF DECAYED TOMATOES (OUT OF 40 IN EACH TREATMENT GROUP)

Storage period (days)	Control		Irradiated	
	GA	Distilled water	GA	Distilled water
25	5	3	6	nil
30	7	4	9	nil
35	10	5	12	nil
40	13	7	14	3

The rate of decay was higher in gibberellic acid-treated, in irradiated as well as in control fruits (Table 5). The decay was mainly due to fungus diseases.

## BIOLOGY

Divisions in Isolated Cells of Palisade Parenchyma of *Arachis hypogaea*

THE exclusive use, up to now, of isolated cells of angiosperms from mechanically separated callus of multicellular origin<sup>1-4</sup> carries the inherent shortcoming that such cells and tissues are patently of artificial origin, environment, and physiology. From every botanical viewpoint, it behoves the investigator of cell morphogenesis to start his experiments with a normal cell. Theoretically, one of the very best starting materials is the mesophyll cell of the angiospermous leaf, the use of which was attempted, unsuccessfully, by Haberlandt<sup>5</sup> more than 65 years ago. Though Haberlandt reported consistent failure in this early attempt, it is difficult to know the reasons for it, beyond the undeniable fact that axenic conditions were not attained, and indeed, were not considered essential by him. Bobiloff-Preisser<sup>6</sup> attempted to repeat Haberlandt's trials, with modifications, but had the same failures. Schmucker<sup>7</sup> reported that the very easily separated mesophyll cells of *Macleaya cordata* divided, yielding groups of a dozen cells in filter-sterilized grated sap of the same leaf. He published no further observations on it. His results, however, were confirmed by Fiedler<sup>10</sup> (p. 382), who presented no photographs. Kandler<sup>11</sup> doubted the foregoing reports and tried the same and other leaves without any success. Once again, Kohlenbach<sup>12</sup> reported the growth of these isolated mesophyll cells in White's medium with coconut water and 2,4-D. His photomicrograph shows a packet of 6–8 cells which he thought were produced by divisions from a single palisade cell. It appears to us that final proof of divisions in the single isolated mesophyll cell is possible only through a photographic record by time-lapse. This has been provided in the present communication.

We agree with the early authors that it is difficult to find leaves suitable for excision of intact, isolated mesophyll cells. We have, actually, tried the leaves of most of the plants growing on the grounds and in the greenhouses of this laboratory and have found that only a few are suitable. Nevertheless, a number of them not only give good excisions, but also show growth and division in some of their isolated cells. Our first success was preaged by the formation of variously-sized spheres of parenchyma in liquid shake cultures of excised mesophyll cells of the peanut, *Arachis hypogaea*. Excisions were then observed in liquid medium\* by time-lapse photomicrography through an inverted phase-contrast microscope at 100× and 200×. Mature leaflets were surface-sterilized in 2.5 per cent sodium hypochlorite, and rinsed in sterile distilled water. They were then drained of most adhering liquid and torn across to expose the mesophyll. Scrapings were

\* Minerals listed as macroelements by Heller<sup>13</sup> (p. 140); those as microelements were, in g per litre of medium: H<sub>2</sub>BO<sub>3</sub>, 0.000066; MnCl<sub>2</sub>·4H<sub>2</sub>O, 0.000086; ZnCl<sub>2</sub>, 0.000156; CoCl<sub>2</sub>, 0.00002; CuCl<sub>2</sub>·2H<sub>2</sub>O, 0.000084; NaMoO<sub>4</sub>·2H<sub>2</sub>O, 0.000025; disodium salt of ethylene dimethyltetraacetic acid, 0.0008; sucrose, 20; casein acid hydrolysate (vitamin-free, salt-free), 0.4; 2,4-dichlorophenoxyacetic acid, 0.001; myo-inositol, 0.1; sorbitol, 0.05; thiamin hydrochloride, 0.0001; pyridoxime hydrochloride, 0.0001; nicotinic acid, 0.0006; choline chloride, 0.01; riboflavin, 0.0001; ascorbic acid, 0.0001; calcium pantothenate, 0.0001; biotin, 0.00001; 'Pyrex'-distilled water to make 1 litre. All components of the liquid were filter-sterilized and never subjected to the heat of autoclaving.

made through the mesophyll by points of microscalpels (Ball<sup>13</sup>) and placed directly into liquid medium in the observation chamber (Ball<sup>14</sup>). The top cover glass was sealed into place and the preparation was placed upon the stage of the microscope. Intervals between motion picture frames were either 2 or 3 min. As in earlier work on *Sequoia*<sup>14</sup> the cells and cell groups soon adhered to the upper surface of the lower cover glass and could then be photographed from below under optimal optical conditions.

For 3-5 days after inoculation, the palisade cell (Fig. 1) showed streaming of cytoplasm which merely moved the large chloroplasts back and forth. Then a localized or overall enlargement occurred. The former often yielded a spherical structure with a filamentous end, the latter an egg-shaped or almost spherical body. Either type of increase caused a loss of the morphological polarity of the cell and of its identity as palisade parenchyma. During this time the chloroplasts increased in size and lost much of their green colour. Mitosis was always preceded by systrophy (cf. Senn<sup>15</sup>); this involved a symmetrical gathering of plastids around the nucleus (Fig. 2). Later, the cell plate developed outwardly from the centrally-located division figure and made contact with the original wall. The new wall had no consistent orientation with the original axis of the dividing cell and was often curved (Fig. 3). Divisions of the derivative cells were also without such orientation (Fig. 4) and the cell-mass produced showed no resemblance to an embryology. The maximum

growth of an isolated cell within the observation chamber yielded 20-30 cells during a period of 14 days. No derivative cell had any resemblance to the palisade parenchyma cell from which it was derived. Dividing cells were exclusively palisade; spongy mesophyll cells showed little change save plasmolysis. The shrinkage is undoubtedly stimulus plasmolysis, as pointed out by Kandler<sup>11</sup>. Boblloff-Preisser<sup>6</sup> (p. 251) stressed the use of the mature leaf in preventing plasmolysis of excised mesophyll cells.

Our results conclusively demonstrate the potential ability to divide in the palisade cell of at least one angiosperm. Similar results by time-lapse have also been achieved from leaves of *Aster* sp., and in shake cultures from leaves of *Erigeron* sp., *Gaillardia* sp., and *Oenothera* sp. Probably the most important prerequisite of successful culture is the facility of removing intact mesophyll cells from the torn-open leaf.

This research programme was supported by the National Institutes of Health.

### Resistance of Tobacco to Stem Infection by *Peronospora tabacina* Adam.

STEM infection with blue mould (*Peronospora tabacina* Adam.) is a serious problem of Australian tobacco crops. Many stem-infected plants are stunted in growth and/or fracture at the base and fall over before the leaves are harvested. Paddick and Hill (unpublished results) concluded from surveys of disease in Victoria that stem infection was a major cause of field loss.

Breeding lines, previously selected on the basis of seedling resistance to leaf infection, were grown at Myrtleford, Victoria, in the 1961-62 season. Many of these lines became stem-infected by blue mould. Thus, in breeding tobacco for resistance to blue mould, consideration should be given to resistance to stem infection as well as to resistance to leaf infection. Fourteen lines which differed in field incidence of stem infection were tested for stem resistance to mould under glass-house conditions. The objective was to assess whether artificial stem infection, as described by Mandryk<sup>1</sup>, could be used in screening breeding lines prior to more extensive field testing. Ten of the lines were normal day-neutral types. The other four were 'mammoth' types, with a short-day requirement for flowering. Seven lines, including one 'mammoth', had derived their resistance from *Nicotiana debneyi* Domin., and six, including three mammoth lines, from *N. goodenopendii* Wheeler by the back-crossing method of plant breeding. The remaining line owed its resistance to the radiation-induced mutation. A highly resistant species (*N. debneyi*) and a completely susceptible tobacco cultivar ('Virginia Gold') were also included in the test.

Seed was germinated on vermiculite, and the seedlings were grown and supplied with nutrients, as described by Hill and Mandryk<sup>1</sup>. Eight weeks after sowing, six plants of each line were stem-inoculated at the base by injecting a suspension of conidiospores of *P. tabacina*. As controls, six plants of each line were stem-injected with distilled water. Plants were kept for 48 h at a temperature of 20° C in an atmosphere nearly saturated with water vapour. After this initial incubation period, the temperature was increased to between 20° C and 29° C and the relative humidity reduced to 70 per cent. Three weeks after injection, the extent of stem infection was determined by measuring the lengths of macroscopically visible necrosis, which had spread from the point of injection, in the cortex, vascular bundles and pith. Except in the highly resistant lines *N. debneyi* and CA229, all the plants injected with spores exhibited stem necrosis.

A comparison of field and glass-house stem infection is shown in Table 1 for the lines with day-neutral flowering requirements.

Table 1. FIELD AND GLASS-HOUSE STEM INFECTION OF DAY-NEUTRAL BREEDING LINES

Code No. of line	Percentage of 100 plants naturally infected in the field	Mean length (cm) of necrosis in 6 plants injected in the glass-house		
		Pith	Vascular bundle	Cortex
<i>N. tabacum</i> cv.				
'V. Gold'	100	14.0	27.0	22.0
<i>N. debneyi</i>	0	0	0	0
CA696	100	3.8	28.8	0.8
M11	100	7.0	17.0	20.0
CA641	80	2.0	4.0	2.0
BA872	78	0.7	8.8	0
CA782	62	0.8	4.8	0
CA681	55	0.0	17.7	0
CA704	54	3.0	19.0	0.2
CA752	30	1.0	5.2	0
CA601	27	0.7	4.5	0
CA229	0	0	0	0

Four lines with high field incidence of stem infection developed appreciable necrosis in pith, vascular bundle, and cortex under controlled glass-house conditions. Five lines with moderate field infection showed necrosis in the pith and vascular bundle only; line CA229, which was not stem-infected in the field, did not develop stem necrosis in the glass-house test. The correlation coefficient of +0.78 (derived from the 12 lines (including 'Virginia Gold' and *N. debneyi*) listed in Table 1) between the percentage of plants infected in the field and the length of necrosis of the vascular bundle in the glass-house test suggests that the stem-injection test could be used as an indication of the susceptibility of breeding lines. There was less agreement between the field infection and the extent of necrosis in either the pith or cortex.

The four 'mammoth' lines showed a higher field incidence of stem infection than would be predicted from their performance in the glass-house test (Table 2). Because of their short-day requirement for flowering they remained in a susceptible condition in the field for a period of six months.

Table 2. FIELD AND GLASS-HOUSE STEM INFECTION OF 'MAMMOTH' BREEDING LINES

Code No. of line	Percentage of 100 plants naturally infected in the field	Mean length (cm) of necrosis in 6 plants injected in the glass-house		
		Pith	Vascular bundle	Cortex
M11	100	1.8	1.7	Tr*
CA694	100	0	8.7	0
DA687	100	0	6.0	0
AA352	87	Tr*	0	0

\* Tr, trace.

Resistance to both the stem and leaf phases of the disease should be considered in breeding tobacco for blue mould resistance. Except in the case of lines which remain vegetative for a long period, the extent of necrosis of the vascular bundle following stem injection under the conditions defined could be used for screening of breeding lines prior to more extensive field testing. One breeding line, CA229, with resistance to blue mould introduced

from *N. goodspeedii*, was shown to be highly resistant to stem infection.

### Role of Growth Regulators in the Uptake and Metabolism of s-Triazine Herbicide by Tea Leaves

In many cases the effectiveness of herbicides has been increased by the addition of surface active agents to the spray<sup>1-4</sup>, but little information is available about the effects of growth regulators on the uptake and metabolism of herbicides by foliage. The object of this work was to investigate the role of gibberellic acid (GA<sub>3</sub>) and indolyl-3-acetic acid (IAA) on the absorption, diffusion, translocation, and metabolism of 2-chloro-4,6-bis(isopropylamino)-s-triazine (propazine) by the upper and lower surfaces of tea leaves, *Camellia sinensis*.

The methods used to study the absorption of <sup>14</sup>C-propazine by detached tea leaves were slightly modified from those described by Biswas<sup>1</sup>, and Biswas and Rogers<sup>2</sup>, to study the absorption of s-triazine herbicides and gibberellic acid respectively. One variety of tea, 'Nyasaaland', was grown at 65°-75° F in the greenhouse until the plants developed 20-25 leaves. At this stage the third leaf from the top was taken for this study. Four hundred ml. of a 0.5 per cent water-agar solution was added to 100 ml. of a solution of propazine, 100 p.p.m., of which 10 ml. was <sup>14</sup>C-labelled. The agar solutions and the herbicide were mixed thoroughly and then poured into petri dishes. The specific activity of water-agar solution containing propazine was 0.035 µc./ml. The total concentration of propazine in the water-agar solution was 20 p.p.m.

One tea leaf per plate was floated on the agar while it was still fluid. High-vacuum grease was applied at the detached end of each leaf to prevent absorption through the cut end. Either the upper or lower surface of the leaves was placed in contact with the agar and permitted to absorb for 24 h under a light intensity of 150 ft.-candles at 28° C. The amount of herbicide absorbed by the leaves in the water-agar solution was determined by the 'Gas Flow 2pi' internal proportional counter.

The leaf samples were cut into small pieces and homogenized in a 'Virtis' homogenizer for 10 min in 10 ml. absolute ethyl alcohol. The homogenate was filtered and one ml. of the filtrate was used for counting. Mixtures of labelled and non-labelled solutions of propazine were prepared and diluted to known concentrations for standard reference solution. The unknowns were calculated with reference to known concentrations of standard solution.

The method used to study the effects of GA<sub>3</sub> and IAA was the same as described above except that one ml. of growth regulator (100 p.p.m.) was added to the water-agar solution together with 50 ml. of a solution of <sup>14</sup>C-propazine, 100 p.p.m.

The diffusion of <sup>14</sup>C-propazine by the upper and lower surfaces of tea leaves with and without growth regulators was obtained by a simple method. The leaves were cut into small pieces and soaked for 24 h in a solution of 16 g ammonium oxalate, 4 g oxalic acid, and 980 ml. distilled water. After 24 h the leaf pieces were boiled over a low flame until the cuticle began to loosen, when the cuticle was removed with forceps. The tea cuticle comes off very easily and uniformly by this procedure. The separated cuticles were then stored in a refrigerator for 24 h and were examined for ruptures under a light microscope before use. The separated cuticle was placed between two rubber

Fig. 1. Diffusion cell apparatus

gaskets under water in a beaker and then placed between two diffusion cells (Fig. 1). In filling the two cells, the outlets were first closed with clamps. One cell was filled with distilled water and the other cell with an equal amount of a 20 p.p.m. solution of  $^{14}\text{C}$ -propazine. To study the effects of growth regulators (GA<sub>3</sub> and IAA) the propazine solution was spiked with growth regulators by the method as described with regard to absorption. The concentrations of propazine which diffused through the separated cuticles were determined by the isotope counting procedure. The concentrations of the unknown samples were calculated from the known standard solutions.

The study of the translocation of propazine was made by autoradiographic techniques. Only the basipetal movement of propazine was studied in this particular experiment. In this case the leaves attached to the plants were floated in the water-agar solution containing 100 p.p.m. of  $^{14}\text{C}$ -propazine (specific activity 2.53  $\mu\text{C}/\text{ml.}$ ) for 40 h in the greenhouse. At the end of 48 h the leaves floated in agar were cut off from the rest of the plant. The plants were placed between blotting papers for 2 days for drying, and then wrapped in 'Cellophane' paper and exposed to X-ray film for 6 weeks.

To study the metabolism of  $^{14}\text{C}$ -propazine, the tea plants were grown in a water culture solution containing labelled propazine for 7 days. At the end of 7 days the plants were harvested, cut into small pieces and homogenized with absolute ethyl alcohol. The homogenate was then filtered and the filtrate was concentrated in a flash evaporator. The concentrated extract was then chromatographed with the original  $^{14}\text{C}$ -propazine as a reference in a solvent system consisting of butanol:acetic acid:water (120:30:50) using Whatman No. 1 paper. The chromatogram was then cut into half-inch sections and the activity of the paper strip was determined by the 'Gas Flow 2pi' internal proportional counter.

The differential absorption of  $^{14}\text{C}$ -propazine by the upper and lower surfaces of tea leaves showed a marked difference in absorption (Table 1). The upper surface absorbed only 3.5 p.p.m. of propazine, whereas the lower surface absorbed 15.0 p.p.m. With the addition of gibberellic acid, increased absorption was obtained in the upper surface, whereas only a slight decrease in absorption in the lower surface was noticed. But with the addition

Table 1. ABSORPTION OF  $^{14}\text{C}$ -PROPAGINE HERBICIDE BY THE UPPER AND LOWER SURFACES OF TEA LEAVES, WITH AND WITHOUT GROWTH REGULATORS

Propazine:	Absorption, p.p.m.					
	Without growth regulators		With gibberellic acid		With indolyl-3-acetic acid	
	Upper	Lower	Upper	Lower	Upper	Lower
	3.5	15.0	9.5	14.5	8.5	16.5

Table 2. DIFFUSION OF  $^{14}\text{C}$ -PROPAGINE BY THE UPPER AND LOWER SURFACES OF TEA LEAVES, WITH AND WITHOUT GROWTH REGULATORS DURING ONE HOUR

Propazine:	Diffusion, p.p.m.					
	Without growth regulators		With gibberellic acid		With indolyl-3-acetic acid	
	Upper	Lower	Upper	Lower	Upper	Lower
	0.23	1.45	0.09	0.27	0.06	0.06

of IAA, both upper and lower surfaces absorbed more as compared to the treatment without growth regulators. As shown in Table 1, both these growth regulators reacted more or less in the same pattern in their effectiveness in absorption.

The amount of propazine diffused through the separated cuticles by the upper and lower surfaces of tea leaves, with and without growth regulators, was more or less the same. In both cases (Table 2) a slight decrease in diffusion was obtained. These results are in agreement with the previous observation<sup>1</sup>. It seems to us from this study that the growth regulators decrease the process of diffusion.

The herbicide propazine, although absorbed in large quantities by tea leaves, is not translocated basipetally. This observation is in agreement with the previous work<sup>1</sup> on peanut plants. Therefore, the toxic effects of propazine seemed to be via root absorption, since this herbicide is absorbed freely through roots and translocated to the different parts of the plants.

In studying the absorption of propazine by the roots and its subsequent metabolism by the tea plant, it was noted that propazine is degraded to form two compounds with  $R_f$  of 0.24-0.28 and 0.46-0.50 respectively. The  $R_f$  value of non-metabolized propazine was 0.96-0.98. Further investigation is in progress to identify and test the bio-activity of these new products and will be reported at a later date. It seems that propazine is easily metabolized by tea plants, giving at least two or possibly more metabolites.

We thank Dr. C. D. Eroegovich, of Geigy Chemical Corporation, for experimental samples of herbicides.

This work was supported in part by a research grant from the National Institutes of Health (EF-00753-01).

## New Method of Recording Germination Data

GERMINATION data are normally published in the form of 'percentage germination'. These are usually, but not always, accompanied by some information on the time taken for the stated percentage to be reached, a typical example being '91 per cent germination in 18 days'. This method is unsatisfactory for two main reasons: (a) It does not facilitate the comparison of germination data published by two authors. Thus, while it is satisfactory within a single investigation, percentage germination in  $x$  days is of little use in comparing different observations except in the unusual case where  $x$  is the same in both. (b) It does not indicate the rapidity of germination but only its final extent. Information which may be important from an ecological or horticultural point of view may thus be lost.

The method proposed is an attempt to record germination data so that a direct comparison between papers will be facilitated and to give in a single figure some indication of the speed of germination as well as its final extent.

The percentage germination is recorded every 24 h. At the end of some suitable time, which must depend to some extent on the species being studied, the results are summed. It has been found with weed species that 10 days is sufficient in that seeds which have not germinated after this time are normally dormant or dead. This gives a figure, recorded as  $\Sigma 10$ , which can vary between 0 (no germination) and 1,000 (100 per cent germination after 24 h). Usually the result is between the two extremes except

# QUICKFIT SCREWCAPS

Quickfit have developed these unique additions to their product range for the purpose of simplifying the assembly of laboratory glassware.

Quickfit plastics screwcaps allow a variety of assemblies to be carried out quickly and efficiently, and serve as an economic alternative to ground glass joints. Their design enables inserts, such as air or steam inlet tubes, stirrers, thermometers etc., to be completely adjustable and yet retain the qualities of a perfect joint. Interchangeable screwcaps with a wide range of thread sizes and insert holes are available. Complete protection from heat and corrosion is provided by PTFE washers.

Write for details of the Screwcap range of Joints, Adapters, Stirrer Glands and Multiple Connectors to Dept. No. N4

*Our chemicals are your business—be it in Gt. Britain or Brisbane*

We have been producing industrial chemicals long enough to know that many of them have a diversity of uses. One industry may use a compound for an entirely different purpose from another. The manufacturer knows his own business best! But the fact remains that Bush chemicals are used in a host of industries in every part of the world. Apart from our established compounds which every good chemist knows we make, Bush research is constantly engaged in developing new compounds... new chemicals—and one industry or another is usually glad of it. Whatever you require, our technical 'know-how' and resources are at your service—wherever you are.

**You know Bush

with completely dormant seed or with seed with exceptionally rapid germination, such as cereals. With some seeds a longer or shorter period may be more suitable which can be recorded as  $\Sigma 20$  or  $\Sigma 5$ , etc.

The results obtained can be statistically analysed by the usual methods, such as chi-squared techniques. If several species are tested using  $\Sigma 10$ , then a direct comparison not only of their germination ability but also of their speed of establishment is obtained. This may be equally important in a study of species growing together since seedling establishment is often one of the most critical stages in the life of the plant.  $\Sigma 10$  will, therefore, often be a function of the competitive ability of the species at this stage. It should also be of use when the effects of dormancy breakers or inhibitors are being studied, since it will give an indication of the overall effect of a germination regulator.

While it is true that if authors recorded germination data on a wide variety of  $\Sigma$  systems comparison of papers would not be facilitated, it seems probable that  $\Sigma 10$  would be a suitable way of recording most data and if this became the convention it would be most useful. Furthermore, if an author found it necessary to record as  $\Sigma 20$  then it would be quite easy to determine  $\Sigma 10$  from this original records if this were later desired. In any event, if  $\Sigma 10$  became the normal method of recording germination data but  $\Sigma 20$  was found to be of greater use in a particular case, it would occupy but little extra space to publish  $\Sigma 10$  also.

### Further Observations on the Caribbean Sponge *Cryptotethya crypta* (de Laubenfels)

RECENTLY, there has been some interest in the Caribbean sponge *Cryptotethya crypta* because of the presence, in extracts of this animal, of a number of unique nucleosides<sup>1,2</sup>: spongothymidine (3- $\beta$ -D-arabofuranosylthymine)<sup>3</sup>, spongouridine (3- $\beta$ -D-arabofuranosyluracil)<sup>4</sup>, and spongosine (9- $\beta$ -D-ribofuranosyl-2-methoxyadenine)<sup>4,5</sup>. During an investigation<sup>6,7</sup> to ascertain whether the sponge possessed an arabinose nucleic acid, it was shown that the ratio of the amounts of ribonucleic acid to deoxyribonucleic acid was the reverse of that found in other animal tissues. This result has been confirmed histochemically<sup>8</sup>, and evidence was presented to indicate the possible presence of an unusual nucleic acid. However, no definite evidence has come forth, as yet, for the existence of an arabinose nucleic acid in this sponge.

Interest in these arabinosides has recently been stimulated by speculations<sup>9</sup> concerning their role in cellular ageing and cancer chemotherapy. An integral part of these speculations is the presumption that an anaerobic mode of existence causes cells to produce arabinosides, which are then incorporated into various cellular components causing irreversible changes in metabolism. Because large amounts of arabinosides had been found in this sponge and, more particularly, because the sponge had been reported to grow more or less covered with sand, it was suggested that at least some anaerobic metabolism may take place in this animal. Our recent findings concerning the habitat of this sponge indicate that its requiring anaerobic metabolism is at least open to question, and some of the other speculations also may have to be re-evaluated.

*Cryptotethya crypta* was first described<sup>10</sup> from the waters around Bimini Island, British West Indies, where it was collected by dredging at a depth of about 5 metres. Search of the bottom using a diving helmet, at that time, showed no indication of its presence. It was concluded

from this, and the fact that the pores and oscules were minute, that the sponge grew under the surface of the sand.

We have collected this sponge on several occasions and have noticed that considerable quantities of algae are usually found growing on its upper surface. The lower surface generally shows signs of having been ripped from a larger piece or a surface to which the sponge had been attached. No specimens have been seen which gave the appearance of having grown unattached, as would be expected for a sponge growing loosely under the coral sand. Specimens without a covering of algal growth are also very rare.

In March 1964, further samples of the sponge were collected at Bimini. 'SCUBA' gear was used, and the area in which the sponge was known to be found by dredging was studied. The bottom is composed of coral ledges which are covered by a thick animal and plant growth. The ledges are interspersed with fairly wide areas of coral sand, the whole presenting a fairly level bottom. On close examination of the coral ledges, *Cryptotethya* was found growing among the algae, firmly attached to the rock, and covered with growth. The sponges, because they blend so extremely well with the surroundings, are very difficult to distinguish.

On dredging a bottom such as that described, the grab traverses both the sandy areas and the ledges. It usually comes up filled with a mixture of sand, algae, and sponges. It is probable that on crossing over the coral ledges, both the sponges and algae are scraped off. When these are then mixed with sand from the other areas, it would not be difficult to conclude that the sponges came from the sandy areas. Later, a few small specimens were found growing in the lagoon east of the island. These sponges, which were growing in relatively shallow water, were found growing in a manner similar to those in the open ocean.

## FORESTRY

### Ultra-thin Sections of Softwood Tracheids and Paper

DURING work on the structure of paper a need arose to examine it in cross-section at high resolution. The sectioning of plant cell walls in their natural state, for example in wood, does not appear to present insuperable difficulties, and techniques based on the early work of Ribi<sup>1</sup> are routinely used. However, no work appears to have been done on the sectioning of pulped fibres, as used in paper, in their dry unswollen state without any pre-treatment. In the skilful work of Asunmaa<sup>2</sup> the fibres were pre-treated by swelling and reaction with thallium ethylate, and after drying from water were dried from benzene, to "open the structure".

We have found that sectioning of untreated paper, using standard techniques of methacrylate embedding, is highly dependent on the pulping process that the constituent fibres have undergone. In the case of paper prepared from pulps that have undergone only the grinding process of fibre separation, sections can be produced quite readily. In the case of paper made from pulps in which the fibre separation is provided chemically by partial extraction of the lignin and hemicelluloses, less satisfactory sections are produced, the least acceptable sections occurring with the most severely degraded pulps. Thus groundwood, consisting typically of 28 per cent lignin and 12 per cent hemicelluloses, produces good sections; a very high yield sulphate pulp produces satisfactory sections and lower-yield sulphate pulps gave rather less satisfactory results. A bleached sulphite pulp containing approximately 85 per cent alpha-cellulose was virtually impossible to section.

The major difficulty in satisfactory sectioning appears to be fragmentation, which appears to occur during the sectioning process. The micrograph of Fig. 1 shows a low-yield sulphite fibre, fragmented and revealing its microfibrillar structure. A possible explanation of this phenomenon lies in the mechanics of the sectioning process. During cutting, the section is constrained to deviate through a large angle and this causes both compression and shear in the section. Under this deformation a plastic material will cut with ease, whereas a brittle material will fragment. It is suggested that a fibre with a high lignin and hemicellulose content will be plastic during cutting, while fibres with a high alpha-cellulose content, consisting substantially of parallel crystalline microfibrillar rods hydrogen-bonded to each other, will be brittle and give rise to fragmentation. This explanation

accords with the recent work of Goring<sup>4</sup> on the thermal softening of lignin, hemicellulose and cellulose.

In an attempt to overcome this problem of fragmentation, a number of other embedding media have been tried. It was found that, using 'Aquan', fragmentation did not occur and satisfactory sections were produced from quite severely degraded pulps (Fig. 2). It was found, however, that by using 'Aquan' for embedding, it was not necessary to cut thin sections. Sections as thick as 1  $\mu$  could be shadowed and inserted into the electron microscope with satisfactory results. It would appear that the heating effect of the electron beam clears the specimen in this case, leaving the shadowing which is effectively a replica of the surface of the section. This clearing, which does not occur with cellulose embedded in methacrylate or any other media that we have tested, indicates that during embedding with 'Aquan' a chemical reaction occurs. The dodecenyl succinic and hexahydro phthalic anhydrides that are used to cross-link 'Aquan' in the embedding process apparently produce a mild esterification of the cellulose, giving a structure that is perhaps thermoplastic and thus does not fragment during sectioning, and one that is more volatile in the electron beam. Embedding with 'Aquan', while of value, cannot therefore be regarded as a method that is free from the criticism<sup>5</sup> that pre-treatment is involved.

## ENTOMOLOGY

### Chemostimulation of Oviposition by the Cabbage Root Fly *Erioischia brassicae* (Bouché)

*Erioischia brassicae* is an important pest of cultivated brassicas, ovipositing in the soil close to host plants. Since all previously known host plants have been confined to the family Cruciferae<sup>1</sup> in which mustard-oil glucosides<sup>2</sup> are characteristically present<sup>3</sup>, it is of importance to know if these chemicals play a part in stimulating the flies to oviposit in the vicinity of the host. It has been shown that among pests of Cruciferae, *Plutella maculipennis* (Curt.) was stimulated to oviposit by a mustard oil<sup>4</sup>, and *Pieris brassicae* L. by an aqueous solution of a mustard-oil glucoside<sup>5</sup>; with both pests, however, the rate of oviposition was much lower than that on host-plant material.

Field and laboratory experiments were therefore carried out to discover whether *E. brassicae* would oviposit only near plants containing mustard-oil glucosides. Eight species of Cruciferae, eight species of other families also containing mustard-oil glucosides<sup>6</sup>, and six species lacking these substances were tested as possible hosts. *E. brassicae* oviposited near all the Cruciferae in the following list, of which only the first two species had previously been recorded as hosts: *Stenobrium officinale* (L.) Scop., *Sinapis arvensis* L., *Sinapis alba* L., *Rorippa nasturtium-aquaticum* (L.) Hayek, *Lepidium sativum* L., *Ocheiranthus cheiri* L., *Cardamine hirsuta* L., *Armoracia rusticana* Gaertn., Mey and Scherb. Flies also laid eggs near *Rosella odorata* L., *R. luteola* L., *Tropaeolum majus* L., *T. peregrinum* var. *canariense*, *Oenothera spinnosa* L., and *C. inornata* L., but no eggs were laid near two species reported as containing mustard-oil glucosides: *Limnanthes douglasii* R. Br. and *Plantago major* L. No eggs were found around the following species lacking mustard-oil glucosides: *Allium*

Fig. 1. Part of a fibre from a low-yield sulphite pulp, showing fragmentation.

Fig. 2. Fibre-to-fibre contact region in paper. 'Aquan' embedding.

*cepa* L., *A. porrum* L., *Beta vulgaris* L., *Vicia faba* L. and *Daucus carota* L. Thus *E. brassicae* oviposited not only near crucifers, including six species not previously recorded as hosts, but also near species of the families Rosaceae, Tropaeolaceae and Capparidaceae that, in common with Cruciferae, contain mustard-oil glucosides. Experiments were therefore made to determine whether a mustard-oil glucoside, and breakdown products associated with mustard oils in plants, stimulated oviposition in the absence of the plant.

The glucoside tested was sinigrin; the breakdown products allyl mustard-oil and  $\beta$ -phenylethylamine\*. Each was presented in aqueous solution between two concentric glass-tubes, thus exposing a meniscus 1 cm in diameter. The tubes were embedded in a jar of damp sand to provide a physical medium for oviposition and to complete the test-unit. One set of test-units containing a range of concentrations of solution were randomly sited, and replaced daily, in cages containing 25 newly emerged flies of each sex. The substances were tested at the following concentrations (p.p.m.):

Sinigrin	0, 25*, 250, 2,500†
Allyl mustard-oil	0, 100, 200*, 400
$\beta$ -Phenylethylamine	0, 10, 100†, 1,000

\* No. *E. brassicae* eggs laid significantly different from No. laid on distilled water test-units at  $P < 0.05$ .

† No. *E. brassicae* eggs laid significantly different from No. laid on distilled water test-units at  $P < 0.01$ .

Eggs were laid on each test-unit, but the following concentrations of chemicals provided more favoured sites: 25 and 2,500 p.p.m. sinigrin, 200 p.p.m. allyl mustard-oil and 100 p.p.m.  $\beta$ -phenylethylamine. These solutions were less effective, however, than juice squeezed from the 'root' of swede (*Brassica napus* L. var *napobrassica* (L.), Rehb.), a favoured host of *E. brassicae*.

These results support the hypothesis that the oviposition preferences of *E. brassicae* are correlated with the presence of mustard-oil glucosides in hosts, while the high rate of oviposition on test-units containing swede juice suggests that chemostimuli provided by plants might be more potent than the physical characteristics of hosts in eliciting oviposition. Each of the three chemicals tested appeared to provide only a partial explanation of the stimulating effect caused by swede juice, and so the stimulating effects of further substances, and mixtures of substances, are being tested.

I thank the National Vegetable Research Station Association for its supporting scholarship, and Mr. D. W. Wright and Mr. T. H. Coaker of the Research Station, and Dr. L. H. Finlayson and Dr. R. W. Murray of the University of Birmingham, for their advice.

### Nitrogen Status of Sugar-cane Leaves and the Fecundity of a Hemipterous Pest

In Jamaica, cane-fly (*Saccharosydne saccharicora* (Westw.) Hom.: Delphacidae) has long been known as a pest of sugar-cane, with records of occasional outbreaks dating back to the nineteenth century. In recent years, however, it has become so prevalent in certain areas that outbreaks can be prevented only by resort to aerial spraying of insecticides on a large scale. Work on the epidemiology of cane-fly has shown that the initial build-up in population occurs most often in plant cane, despite the fact that in such cane the biological pressure of natural

Fig. 1. Broken lines show 5 per cent fiducial limits

enemies is as great as elsewhere<sup>1,2</sup>. The tentative conclusion was, therefore, that the rate of reproduction is an important variant. It is well known that an adequate supply of organic nitrogen is essential for the reproduction of most insects<sup>3</sup>, and that the level of nitrogen in leaf lamina material changes with, *inter alia*, fertilizer treatments, the age of the leaf and the age of the plant<sup>4</sup>. Accordingly, an experiment was designed to determine whether the fecundity of cane-fly was related to the nitrogen content of the leaf.

The experiment was conducted in a glass-house, where sugar-cane was grown in drums which had received different amounts of sulphate of ammonia. Records of the fecundity of a total of 163 cane-fly and the total nitrogen in the leaf were kept for seven months. Newly matured females were caged individually on the third leaf (counting the spindle leaf as No. 1), and the number of eggs laid over a period of about 15 days was noted; fecundity was expressed as the number of eggs laid per day. Two males were caged with each female, and were replaced whenever necessary. Total nitrogen in the third leaf was estimated by the standard micro-Kjeldahl method, and expressed as percentage dry matter.

The results (Fig. 1) show that there is a very significant relationship between the nitrogen status of the leaf and the fecundity of cane-fly. (The scatter of points could probably be reduced by refinements in technique.) An increase from 1.5 to 2.5 nitrogen per cent dry matter, which is the range that is normally encountered under field conditions, results in an increase in fecundity of more than 100 per cent. The increasing importance of cane-fly, therefore, can be attributed at least in part to the improving standard of sugar-cane agriculture and the resulting higher nutritional status of the host plant. The relationship also explains many features of outbreaks, in particular the initial build-up in plant cane, the heavy infestations in young cane, and the population decline as the cane ages. Future work is planned to determine whether it is the amino-acid rather than total nitrogen content of the leaf which is critical, and the relevance

of this to observed differences in varietal susceptibility of sugar-cane to cane-fly.

## MICROBIOLOGY

### Serotypes of *Candida albicans*

THE classification of *Candida albicans* into two serological groups on the basis of agglutination tests was first reported by Hasenclever and Mitchell<sup>1</sup>, and both in the original and subsequent papers<sup>2-4</sup> these authors and their colleagues referred to group A and group B strains. The findings were confirmed by me<sup>5</sup>, using a double-diffusion method, and, for the sake of conformity, similarly using the word 'group' with reference to the serological division within the species. Nevertheless, it must be apparent that this terminology is not consistent with that relating to the serological classification of other microbiological species such as *Pneumococcus* and *Haemophilus influenzae*, where the word 'type' is employed, and that confusion may arise if the word 'group' is used to describe not only an antigen (group antigen) which is common to more than one species of a particular genus, but also the serological division within a species.

There is reason, therefore, for hoping that in any future contributions to this subject the word 'type' or 'serotype' will replace the word 'group'.

### Inhibitory Effect of Dipicolinic Acid on the Anaerobic Oxidation of Glucose by the Cell-free Extract from Vegetative Cells of *B. subtilis*

It has been reported that the dipicolinic acid content of several species of bacterial spores ranges from 5 to 10 per cent of the dry weight of spores<sup>1,2</sup>. The biological actions of dipicolinic acid in spores have been discussed in a few reports. Harrell<sup>3</sup> suggested that the release of dipicolinic acid from spores has some relation to the ability of the organism to oxidize glucose. Harrell, Doi and Halvorson<sup>4</sup> have further shown that dipicolinic acid has a stimulatory effect on glucose oxidation of the cell-free extract of *B. cereus* spores. The relationships of dipicolinic acid content to the heat stability<sup>5</sup> and to the stainability<sup>6</sup> of spores have also been studied.

We wish to report that dipicolinic acid has an inhibitory effect on the anaerobic oxidation of glucose by the cell-free extract from the vegetative cells of *B. subtilis*.

*B. subtilis* (PCI 219) was cultivated on meat extract agar at 37° C for 20 h. Sporulation is known to begin immediately after the 20th h of cultivation under the

conditions employed. The cells were gathered in M/50 phosphate buffer (pH 7.2), washed several times with sterilized phosphate buffer, and finally suspended in M/10 phosphate buffer. The bacterial suspension was then oscillated in a 10-ks sonic oscillator (Kubota 'KMS-100') for 30 min at 2°-3° C. After rupture the vegetative cell brei was centrifuged at 6,000 r.p.m. for 20 min. The supernatant cell-free extract was stored at -20° C before use in enzymatic studies.

The anaerobic oxidation of D-glucose was assayed by measuring the dehydrogenase activity using the Thunberg technique. The side-arm cap contained 0.5 ml. of the cell-free extract containing 2-4 mg protein/ml., 0.1 ml. of 1 M phosphate buffer (pH 7.2), 0.2 ml. of a neutralized solution of dipicolinic acid in varying concentrations, and 0.2 ml. water to make up a total volume of 1.0 ml. The concentrations of dipicolinic acid used were 0.5 M, 0.05 M and 0.005 M. The side-arm caps were incubated for 60, 120 or 180 min at 37° C in order to ensure enough contact of dipicolinic acid with the enzyme preparation before the reaction of the latter with the substrate. The main tubes contained 1.2 ml. 0.025 M glucose, 1.0 ml. 0.01 per cent methylene blue in 1/10 M phosphate buffer (pH 7.2), 0.5 ml. 1 mg/ml. NAD and 0.3 ml. 1 M phosphate buffer (pH 7.2). At the end of the pre-incubation period the tube was thoroughly evacuated, the contents were mixed, and the tube was again incubated at 37° C. The time for complete decolorization of methylene blue was then recorded. In each experiment two different types of control runs were made: (1) dipicolinic acid was omitted, and (2) dipicolinic acid was added to the main tube instead of to the side-arm. The latter type of control experiment was designed to determine the effect of a simultaneous contact of the cell-free extract with both dipicolinic acid and the substrate. The results obtained are summarized in Table 1.

From the results shown in Table 1, it is apparent that dipicolinic acid has an inhibitory effect on the anaerobic oxidation of glucose catalysed by the cell-free extract of *B. subtilis* in the presence of NAD and methylene blue. Two important features of the inhibition noted are: (a) the inhibitory effect is dependent on the concentration of dipicolinic acid (Expts. 1-3), a pronounced inhibition being observed at a concentration of dipicolinic acid as high as 0.1 M in the pre-incubation mixture; (b) the degree of inhibition is markedly increased by a longer contact of dipicolinic acid with the enzyme preparation before incubation with the substrate (Expts. 3-5).

We have further examined whether the inhibitory effect could be found only with dipicolinic acid or with a variety of pyridine mono- and di-carboxylic acids. The compounds tested were quinolinic acid (pyridine-2,3-dicarboxylic acid), lutidinic acid, isocinchomeronic acid (pyridine-2,5-dicarboxylic acid), phthalic acid, nicotinic acid, and isonicotinic acid. The experimental conditions were the same as those described here except that 0.2 ml.

Table 1. INHIBITORY EFFECT OF DIPICOLINIC ACID ON THE ANAEROBIC OXIDATION OF GLUCOSE BY THE CELL-FREE EXTRACT FROM VEGETATIVE CELLS OF *B. subtilis*

The cell-free extract was added to the side-arm cap, and glucose, methylene blue and NAD were added to the main tube

VETERINARY SCIENCE

Seasonal Variation in the Breeding Activity of Rams

Most investigations into the breeding season of sheep in Britain have been concerned with the behaviour of females. Little attention has been paid to the desire or ability of males to mate at different times of the year, for it is generally considered that under temperate conditions there is no discernible non-breeding season in rams of the British breeds.

Present investigations on the natural breeding behaviour of the Clun ewes in the College Farm flock show that the female breeding season commences about the beginning of August and terminates during the second half of March, although there are considerable variations between individuals and between seasons.

On the other hand, a number of ewes have been served during their reputed anoestrous period from the end of March to the beginning of August. Depending largely on time of lambing and earliness of weaning, a proportion of these services have proved fertile, and in earlier observations<sup>1</sup> it was entirely on the basis of autumn lambing that such 'out-of-season' matings were recorded, for the rams then in use were not raddled outside the normal tupping period.

The rams included two Hampshires and one Kerry, and although all three had an equal opportunity to mate with the ewes concerned, every one of 43 late-summer and autumn-born lambs produced over four seasons up to 1962 by 30 ewes was clearly a Kerry cross-lamb.

Both the Hampshires and the Kerry had been effective during the normal tupping seasons, so that this suggested a real difference in the seasonal breeding behaviour of the rams, and possibly the breeds, concerned, but due to the lack of adequate data at the time of service, it was not clear whether the Hampshire rams failed to serve any ewes, or whether they did so but the matings were infertile.

However, since April 1962, when sufficient new rams were introduced to make up two replicates each of a Hampshire, a Suffolk and a Kerry, rams of the respective breeds have worn individual distinctive coloured crayons while accompanying ewes continuously throughout the year. Observations have been made, generally twice a day, of any ewes marked at service, and every 14 days such ewes have been washed clean. In this way separate and continuous service records have been kept for each individual ram.

During the 'anoestrous periods' of 1962-64 an aggregate scatter of 20 ewes were marked, but on every occasion except one the only crayon colour showing has been that worn by a Kerry ram.

This also suggests that while the ewes are 'anoestrous' there is a difference in libido between the Kerry rams and the others. It is possible that the Kerry rams tried to mount ewes whether they were in season or not, but this idea is not supported by the lambing evidence already mentioned.

Specific examples have been recorded among these cases of the Hampshire and Suffolk rams (even when close penned) showing no interest in a ewe which stood to be properly served by a Kerry ram. Nor did the removal of the Kerry, to preclude any possible dominance effect, arouse any interest in either ram of the other two breeds. Nor is the ewe preference factor considered important at this stage. The only ewe preferences recorded have, in fact, been a very few cases in favour of Suffolk rams during the normal tupping season.

During the autumns of 1962 and 1963 no lambings resulted from the recorded 'anoestrous' matings, but this may possibly be partly explained by the fact that during this period no early weaning took place, that is, this could be a ewe factor rather than a ram factor<sup>1</sup>.

Table 3. EFFECT OF DIPICOLINIC ACID ON THE ANAEROBIC OXIDATION OF L-ALANINE BY THE CELL-FREE EXTRACT OF VEGETATIVE CELLS OF *B. subtilis*  
0.5 ml. of cell-free extract containing approximately 4 mg protein/ml. or 0.4 mg protein/ml. was used in Exp. No. 12 or No. 13, respectively

Experiment No.	Side-arm cap Pre-incubation (min)	Dipicolinic acid (μmole)	Substrate	Complete decolorization (min)
12	60	—	D-glucose	17
	60	20	D-glucose	43
13	60	—	L-alanine	11
	60	20	L-alanine	10

0.1 M neutralized solution of the compound to be tested was added to the side-arm cap. The results obtained are shown in Table 2. From the results shown in Table 2, it is apparent that the most potent inhibitor among the compounds tested is dipicolinic acid, while the other three different kinds of pyridine dicarboxylic acids have considerable inhibitory effect (Expts. 6-8). Pyridine monocarboxylic acids and benzene dicarboxylic acid showed little or no inhibition (Expts. 9-11).

We also wished to determine whether the inhibitory effect of dipicolinic acid is specific only for the glucose oxidation. A preliminary experiment of the inhibitory effect on the anaerobic oxidation of L-alanine by the same enzyme preparation was also carried out as an example. The results are shown in Table 3. The data shown in the table indicate that the oxidation of L-alanine is not inhibited by dipicolinic acid.

The results of the present experiment seem to indicate an induced inactivation of the glucose dehydrogenase system by dipicolinic acid of a high concentration *in vitro*, and are of great interest in view of the fact found *in vivo* that during the course of sporulation the accumulation of a tremendous amount of dipicolinic acid proceeds with the concomitant loss of the glucose-oxidizing activity of spores<sup>2</sup>.

Further investigation will be needed as to the mechanism of inhibition of the glucose oxidation by pyridine dicarboxylic acids, particularly by dipicolinic acid.

This work was supported in part by a grant from the Ministry of Education, Japan.

<sup>7</sup> Hachisuka, Y., Asano, N., Kaneko, M., and Kanbe, T., *Science*, **134**, 174 (1956).

Not only have the Kerry rams appeared to be the only active rams during the 'out-of-season' period but they have also appeared to be quicker off the mark at the onset of the normal breeding season. For example, in 1963, by the day on which all three rams had begun to work, a Kerry ram had already served seven ewes over a 10-day period and a Hampshire only one; while in 1964 a Kerry had already served eight ewes over a 14-day period and a Suffolk only two.

There thus appears in these particular rams to be a real difference, during the 'anoestrous period' of the ewes, between the sexual behaviour of the Kerry rams on the one hand, and of the Hampshires and Suffolks on the other. Either the Hampshires and the Suffolks have been almost totally lacking in libido at this time or the ewes concerned have not exhibited a degree of heat detectable by them though it has apparently been patent enough for the Kerrys.

It is not known whether these differences between the rams are associated with differences in semen quality, but semen samples have been collected by electroejaculation from two other replicates of similar groups of rams at fortnightly intervals from November 1963 to November 1964 and the results of this work are now being examined.

## PSYCHOLOGY

### Substitution of Intracranial Electrical Stimulation for Photic Stimulation during Extinction Procedure

It has been demonstrated that a conditioned response to a peripheral physiological stimulus (CS) can later be evoked when electrical stimulation of the cortical or subcortical centres is substituted for the original conditioning stimulus<sup>1-3</sup>. The present experiment was designed to examine the degree to which electrical stimulation of the occipital cortex, during the extinction stage of an avoidance conditioning procedure, would elicit conditioned responses (CRs) in an animal previously trained to respond to light (CS).

Ten male albino rats, 150-180 days old, with bipolar electrodes chronically implanted in the occipital cortex, were used. The electrodes, insulated with 'Teflon' except at the very tip, were approximately 150 $\mu$  in diameter. Histological examination showed that the electrodes were in the visual cortex about 0.5-1 mm deep from the surface.

Initially, all animals were trained, in a Skinner box, to press a lever to avoid a mild shock to the feet when a light (CS) was presented. The floor of the box had grids through which the foot shock (US) was delivered. The light emitted by two 25-W bulbs mounted in the box was used as the CS. This light was sufficient to illuminate the interior of the box fairly uniformly. Each trial was initiated by the onset of the CS for 5 sec, after which the US was delivered. Both the CS and the US continued until the animal pressed the lever. If the animal failed to respond within 50 sec after the onset of the US, the CS and US were terminated automatically and it was counted as a trial.

The CR was a lever press within the initial 5 sec of the CS presentation. Forty trials were administered per day with intertrial intervals of 20-40 sec. Animals were trained to make 80 per cent CRs per day for two consecutive days. The day after the last conditioning day, the animals were tested for generalization to electrical stimulation of the occipital cortex. On the test day, the CS-US paired trial was administered for the first

No. conditioning trials	No. extinction trials to the test stimulus	No. extinction trials to the CS
160	8	—
240	20	—
400	0	—
880	12	—
440	0	—
240	16	72
160	13	49
480	0	286
160	25	57
160	40	80

20 trials. Immediately after the 20th trial, the extinction procedure (without a foot-shock) was started. In this procedure, electrical stimulation of the occipital cortex (test stimulus) was substituted for the original CS (light). The test stimulus consisted of a train of biphasic waves of 3 msec duration and a frequency of 35 c/s. The intensity varied among animals between 10 and 120  $\mu$ amp. The test stimuli were below the threshold for any visible behavioural signs such as a cessation of movements or the appearance of tremors. For each extinction trial, the test stimulus was presented for a maximum of 5 sec. A lever press within this time was scored as a CR. The extinction procedure was terminated when animals failed to make CRs for six consecutive trials. Immediately after extinction to the test stimulus, five animals were subjected to additional extinction trials to the original CS (light). The criterion for the extinction was again six consecutive trials without a CR.

Table 1 shows the number of conditioning trials (column 1), extinction trials to the test stimulus (column 2), and extinction trials to the original CS (column 3). Seven out of ten animals trained to the light stimulus showed generalization to the test stimulus. The degree of generalization varied considerably among the subjects (from 8 CRs to 40 CRs). For the group as a whole, there was no correlation between the intensity of the stimulating current and the number of the CRs elicited ( $P$ ,  $-0.31$ ). The three subjects which failed to show generalization to the test stimulus failed also to show any other detectable effects of the stimulation even when the intensity was raised to 120  $\mu$ amp. This may indicate that the failure of three animals to generalize was due to a lack of an adequate stimulation of the neural tissues. The five animals that were subjected to additional extinction trials using the original CS (light) elicited a large number of CRs. For these animals, there was no significant correlation between the number of extinction trials to the test stimulus and the number of extinction trials to the original CS ( $P$ ,  $-0.1$ ).

These findings agree with previous findings that the intracranial stimulation can be substituted as CS to evoke conditioned responses previously trained to a peripheral physiological stimulus. Studies on stimulus generalization have demonstrated that generalization (a) is a decreasing function of the differences between the original and the test stimulus, and (b) varies directly with the degree of original learning. The present results, however, indicate that the generalization to the intracranial stimulation used as the test stimulus is not related to the number of acquisition trials or to the intensity of the stimulating current. This may be due to the fact that the neural excitation produced by the direct intracranial electrical stimulation is quantitatively as well as qualitatively different from that produced by the peripheral physiological stimulation.

I thank Drs. F. Morin and D. Asdourian for their advice. This work was supported by U.S. Public Health Service grant MH-05799 and by the National Council to Combat Blindness, Inc., SF 241.

## FORTHCOMING EVENTS

Saturday, July 17—Sunday, July 18

BRITISH ACADEMY OF FORENSIC SCIENCES (at the London Hospital Medical College, New Hall, Ashfield Street, London, E.1.)—Sixth Annual Scientific Meeting. Main theme—"Poisons and Poisoning".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT EXPERIMENTAL OFFICER (preferably with a knowledge of chromatographic techniques) to assist in developing and applying analytical techniques for insecticide residues, and to aid in studies on the behaviour of insecticides in soils and plants.—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (July 17).

ASSISTANT LECTURER or LECTURER AT THE TIDAL INSTITUTE AND OBSERVATORY for research on the mathematical theory and numerical analysis of tides and kindred phenomena.—The Registrar, The University, Liverpool, quoting Ref. OV/169/N (July 17).

ADMINISTRATIVE ASSISTANT (preferably with some familiarity with the notations and terminology of higher mathematics) IN THE DEPARTMENT OF MATHEMATICS.—The Registrar, The University, Leeds, 2 (July 19).

RADIATION PROTECTION OFFICER (physicist, physical chemist, biophysicist, health physicist, or other suitably qualified person).—The Registrar, The University, Nottingham (July 19).

LECTURER (with a good honours degree and experience in teaching, research or industry, or a postgraduate qualification) IN PHARMACOLOGY.—The Registrar, Brighton College of Technology, Moulsecomb, Brighton, 7 (July 20).

POST-DOCTORAL FELLOW (with experience in plasma physics, microwave techniques or electromagnetic theory and use of a computer) in a plasma physics group which is studying the scattering of microwaves by various plasma configurations.—The Registrar, University College of Wales, Aberystwyth (July 20).

DEMONSTRATOR IN THE DEPARTMENT OF VETERINARY SURGERY.—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh, 8 (July 21).

RESEARCH ASSISTANT (graduate in zoology) IN ZOOLOGY to undertake research on ecology of Collembola in woodland, probably in Huntingdonshire, starting September 1965.—Head of the Department of Botany and Zoology, Sir John Cass College, Jewry Street, London, E.C.3 (July 21).

UNIVERSITY DEMONSTRATOR (with a registrable qualification in veterinary medicine or an honours degree in pharmacology or a related subject) IN THE DEPARTMENT OF VETERINARY PHARMACOLOGY, Royal (Dick) School of Veterinary Studies.—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (July 21).

RESEARCH ASSISTANT (with a good honours degree, some postgraduate experience, and preferably an interest in physiological mycology and/or soil microbiology) IN THE DEPARTMENT OF BOTANY, Queen's College, Dundee.—The Secretary, University of St. Andrews, Queen's College, Dundee (July 24).

RESEARCH ASSISTANT (with a Ph.D. degree in chemistry) to work with Dr. J. S. Whitehurst on steroids.—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (July 24).

LECTURER (with an honours degree in physiology or closely allied subject, and preferably some research experience) IN THE DEPARTMENT OF PHYSIOLOGY.—The Secretary, The University, Edinburgh (July 26).

LECTURER (with previous experience in forensic medicine and general pathology) IN THE DEPARTMENT OF FORENSIC MEDICINE.—The Secretary, University of Edinburgh, Edinburgh (July 28).

RESEARCH ASSISTANT (with an honours degree in chemistry and an interest in biochemistry) IN THE DEPARTMENT OF FORENSIC MEDICINE, to assist in a programme of research into the development of rapid methods of toxicological analysis.—Dr. Harold V. Street, Department of Forensic Medicine, University New Buildings, Teviot Place, Edinburgh (July 30).

SECOND CHAIR OF CHEMISTRY (candidate's interests should be either in physical or inorganic chemistry).—The Registrar, The University, Hull (July 30).

SENIOR LECTURER or LECTURER and LECTURERS or ASSISTANT LECTURERS (3) IN GEOGRAPHY at the University of the West Indies (Mona).—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (July 30).

SENIOR LECTURER, LECTURERS or ASSISTANT LECTURERS (with an appropriate qualification and/or experience in one or more of the following fields: taxonomy, ecology, genetics, cytology or general botany) IN BOTANY at the University of Ife, Nigeria.—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (July 30).

ASSISTANT (B.Sc. honours biochemistry or with biochemistry in ordinary degree, familiar with fractionation techniques, and preferably experience in protein chemistry) for a study in bacterioid purification.—The Secretary, Glasgow Royal Infirmary, 84 Castle Street, Glasgow, G.4 (July 31).

ASSISTANT LECTURER (medically qualified or non-medically qualified) IN MEDICAL GENETICS to be responsible for cytogenetics.—The Registrar, The University, Manchester, 13, quoting Ref. 188/65 (July 31).

FAULTY LECTURESHIPS (2) IN MATHEMATICS (each lectureship will be held with a stipendiary fellowship at an Oxford college).—The Secretary of Faculties, University Registry, Broad Street, Oxford (July 31).

LECTURER or ASSISTANT LECTURER (preferably with interests in a branch of pure mathematics) IN MATHEMATICS IN THE SCHOOL OF MATHEMATICS AND PHYSICS.—The Registrar, University of East Anglia, Norwich Hall, Norwich, NR8 88c (July 31).

LECTURERS and ASSISTANTS IN ZOOLOGY.—Secretary of the University Court, The University, Glasgow (July 31).

SCIENTIFIC OFFICERS (2) (with a good honours degree, preferably in physiology or biochemistry and/or a veterinary qualification, 1965 graduates would be considered) IN THE PHYSIOLOGY DEPARTMENT to undertake work on (1) the endocrine control of mineral metabolism, and (2) the physiology of digestion in farm animals.—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen, Scotland (July 31).

CHAIR OF AGRICULTURAL BIOLOGY at Makerere University College, Uganda.—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (August 15).

CHAIR OF BIOCHEMISTRY, CHAIR OF SOCIOLOGY, and SENIOR LECTURERS, LECTURERS or ASSISTANT LECTURERS IN AGRICULTURAL BIOCHEMISTRY and BIOCHEMISTRY at the University College of Rhodesia and Nyasaland.—The Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (August 15).

CHAIR OF SOCIAL ANTHROPOLOGY IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY AND AFRICAN ADMINISTRATION, University of the Witwatersrand,

Johannesburg, South Africa.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 30).

LECTURER (graduate in science, medicine or veterinary science, and preferably possessing a higher qualification and experience in teaching and research in pharmacology) IN PHARMACOLOGY at the University of Queensland, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, August 27).

CHAIR OF PHARMACOLOGY at the University of the Witwatersrand, Johannesburg, South Africa.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 31).

LECTURER (preferably theoretical physicist with experience in crystals or solid state physics) IN PHYSICS.—The Secretary, University of St. Andrews, Queen's College, Dundee, Scotland (August 31).

LECTURER IN PSYCHOLOGY at the University of Canterbury, Christchurch, New Zealand.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, August 31).

LECTURER (preferably theoretical physicist with experience in crystal or solid state physics) IN PHYSICS in Queen's College, Dundee.—The Secretary, University of St. Andrews, Queen's College, Dundee (August 31).

POST-DOCTORAL RESEARCH FELLOW IN THE DEPARTMENT OF INORGANIC CHEMISTRY, University of Melbourne, Australia.—The Registrar, University of Melbourne, Parkville, N.S. Victoria, Australia (August 31).

SENIOR LECTURER/LECTURER (with an honours degree in physics or textile physics or equivalent qualifications, and for the appointment as Senior Lecturer a higher degree is essential) IN THE SCHOOL OF TEXTILE TECHNOLOGY, University of New South Wales, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 31).

SENIOR LECTURER or LECTURER IN EDUCATION at Victoria University of Wellington, New Zealand.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, August 31).

LECTURER (with an honours degree in optometry or equivalent qualifications, some clinical experience, and preferably teaching and/or research experience) IN THE DEPARTMENT OF OPTOMETRY, School of Physics, University of New South Wales, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 20).

SENIOR LECTURER (with an honours or higher degree in physics or metallurgy with research and/or teaching experience in the field of metal physics) IN METAL PHYSICS IN THE DEPARTMENT OF METALLURGY, University of Melbourne, Australia.—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London) (September 30).

SENIOR LECTURER (with special interests in physical oceanography, including dynamic oceanography and/or marine geology) IN OCEANOGRAPHY; and a LECTURER (preferably with a special interest in cosynology) IN BIOGEOCHEMISTRY.—The Registrar, University College of Swansea, Singleton Park, Swansea (October 1).

ASSISTANT CONSERVATOR OF FORESTS (national of the United Kingdom or the Republic of Ireland, with a degree in forestry) in Uganda, for the organization, administration and technical management of forest operation in a district of Uganda.—The Appointments Officer, Room 301, Ministry of Overseas Development, Bland House, Stag Place, London, S.W.1, quoting RO 324/183/01.

ASSISTANT LECTURER IN INORGANIC CHEMISTRY.—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

CHIEF TECHNICIAN IN THE DEPARTMENT OF CHEMISTRY for duties concerned with the purchase of materials and supervision of laboratories.—Prof. J. N. Bradley, Department of Chemistry, University of Essex, Wivenhoe Park, Colchester, Essex.

RESEARCH ASSISTANT or PHYSICIST to work as assistant to the Head of the Electronics Unit of the Physics Department.—The Assistant Secretary, St. George's Hospital, London, S.W.1.

FELLOW IN THE CHEMISTRY DEPARTMENT, for work which will involve the application of far infra-red spectroscopy to problems in inorganic and physical chemistry, under the direction of Dr. A. Finch.—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

FIELD GEOLOGIST (national of the United Kingdom or the Republic of Ireland, with an honours degree in geology and five-ten years field experience in modern prospecting techniques including diamond drilling, geochemical and geophysical methods) in Jordan, to train a Jordanian field geologist in the principles of mineral research in the field, and in the running of a Mobile Prospecting Unit.—The Appointments Officer, Room 301, Ministry of Overseas Development, Bland House, Stag Place, London, S.W.1, quoting RO 318/94/03.

GRADUATE ASSISTANT IN BIOCHEMISTRY to assist with the investigation of the metabolism of surgical patients in infancy and early childhood.—The Secretary, Institute of Child Health (University of London), Great Ormond Street, London, W.C.1, quoting Ref. 8/GAB.

GRADUATE RESEARCH ASSISTANT in the field of mammalian neuro-anatomy in the Zoology Department. The work will entail the use of histological, histochemical and experimental techniques.—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

HOLT FELLOW (graduate in medicine or science) IN PHYSIOLOGY to collaborate in research into the electrophysiology of mammalian muscle spindle receptors and assist in the development of a new research unit for investigating the pharmacology of the muscle spindle.—The Registrar, The University, Liverpool, 3, quoting Ref. OV/168.

LECTURER IN THE DEPARTMENT OF ZOOLOGY at Fourth Bay College (The University College of Sierra Leone).—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1.

LECTURER or ASSISTANT LECTURER IN THEORETICAL PHYSICS.—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey.

LECTURER (well qualified academically with postgraduate experience in industry and/or teaching) IN PHYSICAL CHEMISTRY to teach to B.Sc. and Grad.R.I.C. Part II level.—The Principal, Midway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

OFFICER (with a degree in horticulture, agriculture or agricultural botany, or other equivalent qualifications) FOR VEGETABLE TRIALS, to be stationed at Cambridge and will be responsible under the Head of the Trials Branch for the organization and supervision of the vegetable variety testing programme of the Institute.—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

**RESEARCH ASSISTANT** (preferably with some competence in quantitative chemical analysis) to participate in physiological work with a biochemical bias—The Administrator, University Laboratory of Physiology, Oxford.

**RESEARCH BURSARY IN THE CHEMICAL ENGINEERING AND CHEMICAL TECHNOLOGY DEPARTMENT** for studies on the mechanism whereby certain additives render plastics non-inflammable—Dr. C. F. Collins, Imperial College of Science and Technology, London, S.W. 7.

**RESEARCH FELLOW IN THE DEPARTMENT OF CHEMISTRY** to work under the direction of Dr. R. Foster on studies of organic charge-transfer complexes—The Secretary, University of St. Andrews, Queen's College, Dundee.

**RESEARCH STUDENTS AND POST-DOCTORAL WORKERS IN THE DEPARTMENT OF MICROBIOLOGY**, for studies of microbial chemistry in relation to pathogenicity and immunity—Prof. H. Smith, The University, Edgbaston, Birmingham, 15.

**RESEARCH STUDENTS** (men or women) in the Department of Physics—The Secretary, Royal Holloway College (University of London), Egham, Surrey.

**RICE AGRONOMIST** (national of the United Kingdom or the Republic of Ireland, with an honours degree in agriculture or horticulture, one or two years postgraduate training, and preferably field experience with tropical crops) in Sarawak, to design and conduct experiments on wet rice and, to a lesser degree, on hill (dry) rice and off-season crops—The Appointments Officer, Room 801, Ministry of Overseas Development, Maud House, Stag Place, London, S.W.1, quoting ref. RO 213/155/03.

**SPECIALIST TECHNICIAN** for an instrument workshop concerned with design, construction and maintenance of specialised laboratory equipment—The Secretary, Institute of Psychiatry, The Maudsley Hospital, Denmark Hill, London, S.E.5.

**TECHNICAL ASSISTANT** (preferably graduate with some knowledge of biochemistry) for a research team working in the Department of Biochemistry—The Secretary, The University, Edinburgh.

**TECHNICAL OFFICERS** (with at least H.N.C. metallurgy) for basic and applied work in the field of making and properties of coatings—G. F. Waters, Department of Industrial Metallurgy, University of Birmingham, Edgbaston, Birmingham, 15.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

- Micro X-Radiography and Analysis Bibliography, 1918-1963. By R. V. Hey. (Guildford: R. V. Hey, 22 Hunsimere Avenue, 1963.) [56]
- Proceedings of the First European Malacological Congress, London, September 17-21, 1962. Edited by L. B. Cox and J. F. Peake. Pp. vii + 266. (London: The Malacological Society of Great Britain and Ireland; and The Malacological Society of London, 1963.) 40s.; 6 dollars. [105]
- The British Iron and Steel Research Association. Annual Report for the year ending December 31, 1964. Pp. 182. (London: The British Iron and Steel Research Association, 1965.) [106]
- Collaborative Tests. Report of a Symposium held at the School of Pharmacy, Brighton College of Technology, May 30, 1964. Pp. 68. (London: The Pharmaceutical Press, 1965.) 12s. 6d. [106]
- Farm Animal Welfare and World Food: Evidence tendered to the Committee of Enquiry on Intensive Livestock Husbandry. By J. R. Bellamy. Pp. 60. (London: One World Publications, 1965.) 6s. [106]
- National Union of Journalists. Freelance Directory 1965. Pp. ii + 118. (London: National Union of Journalists, 1965.) [106]
- European Brewery Convention. Report of the Barley Committee—Trials 1963. Pp. 184. (London: The Institute of Brewing, 1965.) [106]
- University of Liverpool. Annual Report of the Tidal Institute and Observatory 1964. Pp. 20. (Liverpool: University of Liverpool, 1965.) [106]
- Report of the Astronomer Royal for Scotland for the year ending 31st March 1965. Pp. 18. (Edinburgh: The Royal Observatory, 1965.) [106]
- Building Research Station Digest (Second Series). No. 57: Painting Walls—8. Pp. 4. (London: H.M. Stationery Office, 1965.) 4d. [105]
- University of Cambridge, Department of Engineering. Report of the Head of the Department for the year 1963-64. Pp. 14. (Cambridge: The University, 1965.) [106]
- The Engineering Institutions Joint Council. Annual Report of the Joint Council for the year 1964. Pp. 6. (London: The Engineering Institutions Joint Council, 1965.) [106]
- National Institute of Oceanography. Collected Reprints, Vol. 12. Reprints 467-508. (Wormley, Godalming. National Institute of Oceanography, 1964.) [106]
- English Special Report from the Estimates Committee, Session 1964-65. The Forestry Commission—(Departmental Observations on the Seventh Report from the Estimates Committee in Session 1963-64) Pp. 8. (London: H.M. Stationery Office, 1965.) 9d. net. [285]

## PUBLIC AND PRIVATE ENTERPRISE IN DEVELOPING COUNTRIES

THE debate on the Commonwealth in the House of Lords on May 5, opened by Lord Casey, was notable for the warm tributes to the work of the Commonwealth Development Corporation by Lord Casey himself, Lord Wade, Lord Fraser of Lonsdale, and Lord Howick of Glendale, who took up the suggestion that the Corporation should attempt to bring together modern scientific ideas on tropical agriculture on a large scale with a social system of small holders, and said that this had been done in Malaya, Swaziland and Kenya, and that the Corporation hoped to do it in Nigeria. For the Government the Lord Chancellor and Lord Taylor particularly emphasized the extent of the work of the British Council in the Commonwealth, while the Lord Chancellor referred to the initiatives for a Commonwealth Secretariat, a Commonwealth Foundation and a Commonwealth Medical Conference which had come from the Prime Minister's Conference in 1964. In that year Britain's total bilateral aid, including technical assistance, was £174 million, of which £108 million was to the independent territories of the Commonwealth, including 72 per cent of our technical assistance programme. Under the present Government about £20 million of Britain's capital aid had been pledged to developing Commonwealth countries. Apart from this reference to financial aid the Lord Chancellor's main emphasis was on the encouragement of personal contacts, and this theme was taken further by Lord Taylor in relation to the interchange of students. He also mentioned family planning and said that, under the auspices of the United Nations, a five-man team led by Sir Colville Devereil had been sent to India in February 1965, at the invitation of the Indian Government, to advise on the course of action to make small families more acceptable, to encourage the practice of family planning and to reduce the national birth-rate. The team's report was now being prepared. Lord Taylor added that the Consultative Committee of the Colombo Plan had chosen for their topic for their next winter meeting the relation between population and economic development.

The debate on overseas investment on the following day was intended to call attention to the importance of British private investment, and in opening the debate Lord Aldington was particularly concerned with the possible adverse effects on overseas investment, and in consequence on Britain's future exports, of the clauses in the Finance Bill relating to corporation tax on overseas investment. Lord Aldington discussed fairly enough the advantages which accrue from overseas investments and also the disadvantages, and his concern was shared by other speakers. For the Government, Lord Shepherd welcomed the debate but maintained the Government's view that, for a relatively short period, Britain should curb her investments overseas, both on account of the balance of payments situation and to ensure sufficient investment for her own industries to strengthen her economy. None the less, his speech did not satisfactorily cover the points raised subsequently by Lord Chandos, Lord Kilmuir and Lord

Amory, nor were they fully met by the Earl of Longford in replying on the debate for the Government.

This debate, notably objective and free from party politics, gives the greater interest to a recent publication of the Overseas Development Institute, *Investment and Development*, in which the role of private investment in developing countries is discussed\*. Following an introduction by Sir Leslie Rowan, Mr. W. Clark considers the limitations attached to Government effort, Sir Jock Campbell discusses the role of big business in the new nations, Mr. J. H. Loudon the place of international enterprise in the development decade, and Mr. A. Gaitekall writes on how to make the best of capital risk in the developing countries. The uncertainty about the future of official aid, which appears to be levelling off partly because of balance of payments problems and partly because of disillusionment as to the effectiveness with which the aid has been used, encourages a re-appraisal of private investment which at one time was considerably circumscribed by political uncertainties. Sir Leslie makes the sound point that if private investors in Britain are to accept such a responsibility they must be provided with the wide knowledge on which the deep study leading to a conscientious and informed discussion can be based. There must also be frank public discussion of every aspect of the situation, including both profit and the use of trained manpower, and it is as a contribution to such discussion and the subsequent framing of continuous policy that the booklet is published.

Mr. Clark begins by noting that while aid in the form of public investment in the underdeveloped countries has been steadily increasing, private investment has been falling off. This is dangerous primarily because it may retard the whole process of development so that it falls below the increase of population or only just keeps pace with it. It is unlikely, moreover, that the Government will increase aid from public funds to fill any such gap, nor is it certain that Government aid alone would be adequate. Private investment retains certain advantages which public aid cannot easily match, and the Clay Committee in 1963 affirmed its conviction that it is the private sector, operating with the co-operation of a vital and democratic labour movement and enlightened management, on the basis of essential government services and sensible policies, which will make the greatest contribution to rapid economic growth and overall development.

Much the same point is made by Mr. Loudon, who comments that the ultimate solution to the world's economic problems is a huge increase in trade, and that State aid is limited by what taxpayers will accept. He pinpoints the significance of this whole discussion of overseas aid in the light of the proposals of the Finance Bill now before Parliament. He points out, moreover,

\* *Investment and Development: The Role of Private Investment in Developing Countries.* Sir Leslie Rowan, J. H. Loudon, Sir Jock Campbell, Arthur Gaitekall, and William Clark. Pp. 60 (London: Overseas Development Institute, 1965.) 7s. 6d.

that industrial investment tends to promote the local creation and sharing of expertise, divorced from political motives or ideology, though he recognizes that the attitude of some Governments to the whole private sector is sometimes a serious difficulty. A Government's role, Mr. Loudon believes, is to direct and liberate the energies of the people. Governments of developing countries must reconcile economic growth with reasonable financial stability, and they must also promote structural changes far more sweeping than are needed in the industrialized countries.

Mr. Loudon refers in passing to fears of the power of big business which he regards as ill-founded, but this question is discussed more fully by Sir Jock Campbell, who reminds us that modern big business is an economic grouping of men and women existing to produce and manufacture goods, to provide services and to distribute goods. To do this successfully its managers must recognize and fulfil responsibilities to shareholders, to employees and to customers, as well as to the community within which the business operates and in which it is rooted. Profits, and with them efficiency and productivity, are not ends in themselves but criteria—incisive instrumental means towards intelligible ends.

From this Sir Jock develops his view that there are projects necessary for the development of a country which, while not losing money and inappropriate for public subsidy, do not offer a commercial return on investment. They are appropriate either for State enterprise through public corporations, or for partnership between State and private enterprise on special terms, though he sees no reason why the State should not participate actively also in undertakings which promise to be profitable. It has to be remembered, moreover, that in establishing a great industry in an underdeveloped country a new way of life and a new series of motives, activities and disciplines are imposed on the people. Private property, punctuality, financial honesty, financial incentive, productivity, efficiency, technical invention and discipline, regularity, regimentation; all these may be new and strange as well as necessary. In practice a synthesis is required between the inevitable demands of industrialization, the inherent values and standards and culture of the new nations, and the aspirations and associations of nationalist leaders. Probably the critical factor, though Sir Jock does not mention this, is how long we can allow for this synthesis.

This situation is examined in greater length by Mr. Gaitskell in the final paper in the booklet, considering more especially the objectives of the African countries and the role of the West in achieving them. He emphasizes the need for a joint capital structure and suggests that there are four main requirements if we are to build a superstructure which can turn the inert base or infrastructure, which overseas aid has already done so much to provide, into higher standards of living, a superstructure which Africans can call their own. These requirements are: modernization of agriculture; education of personnel, particularly middle-group technical personnel, to execute such a programme; capital investment in agriculture and industry; and market openings for the products. The scope for private investment lies in both agriculture and industry. The market openings depend on a real drive to encourage world trade.

Mr. Gaitskell suggests that national policy might well evolve as a result of several convergent steps. First, more emphasis that the ultimate purpose of Western world

policy is to enable developing countries to stand on their own feet, and less on persuasion that we have the best answer to civilization. A second and new approach to the problem of mutual co-operation in investment is called for, with a general objective of promoting local control of the economy but on a broad basis, avoiding alliance between foreign private enterprise and local industrial oligarchies. It would include such remedies as joint capital structure and it would seek to harness private capital as an ally in development. Third, with this approach stronger pressure could be brought to bear on developing countries to accept and set up national plans of development which could integrate and control competing and conflicting external offers of aid. Fourth, clear co-operation between those who assist and plan expenditure on the infrastructure, whether internal or national agencies, and those who supply the public or private enterprise which must follow. Fifth, national discouragement of balkanization and encouragement of inter-African co-operation are particularly important; and sixth, mutual endeavour to avoid lop-sided development which appears to be one of the greatest present problems in the developing world. Seventh, Mr. Gaitskell puts active measures to increase the ability of developing countries to sell their products remuneratively in the developed world. Eighth, the terms of aid need overhaul to remove any impression that the developed countries' interests are dominant. Ninth, dispassionate enquiry into the necessity and feasibility of birth control; tenth, a forum for frank discussion of all these problems with African leaders instead of the separate conferences of developed and developing countries; and last, much more publicity in the Western world as to the complexity and importance of a new look at its relations with the developing world.

It is apparent from the two debates in the House of Lords that to some extent action is already being taken on some of these lines. The debates themselves, like the booklet, should assist the process of education and publicity. It is no less clear, however, that changes in Britain's own national policy require careful consideration from the point of view of their effects on world trade and on the developing world and not solely on our domestic situation. That makes it the more desirable for such discussion to be as free as possible from the heat of party politics. The debate in the House of Lords on May 6 demonstrated that this is practicable, given goodwill.

The programme "Second Thoughts on Aid" which was broadcast on the B.B.C. Third Programme in April and May is an important contribution to public discussion of the whole subject and covered many of the points raised in the papers in the Overseas Development Institute booklet and in the House of Lords. The role of private investment was the subject of the fourth discussion, for example, and the special problem of agriculture was considered in the sixth programme in the series. Technical assistance and priorities of education formed the subjects of the next two, and in the fifth the economic role of international institutes was discussed. The political aspects were considered in the opening two discussions which dealt with the politics and philosophy of donor countries and with some political realities of recipient countries, respectively. The whole series is well designed to stimulate interest and to promote the informal discussion and public understanding which are essential if the necessary support is to be forthcoming for the effort which Britain must make in this field.

## GENETICS AND THE BIOLOGICAL FRONT

### Advances In Genetics

Vol. 12. Edited by E. W. Caspar and J. M. Thoday. Pp. viii+388. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 100s.

VOLUME 12 of *Advances in Genetics* exhibits very well both the strengths and also the weaknesses of this type of annual publication. In a total of nearly 400 pages it contains only four articles, of which the two longer concern general problems and the two shorter quite specialized and restricted special fields. The coverage is very wide, from the stringently intellectual molecular biology to the most 'biological' plant systematics and genetics. There is probably no biologist alive who will be equally interested in all four articles. It is worth considering what various types of readers can get out of them.

The first is by Frank Lanni on "The Biological Coding Problem". It is not more than about four years ago that the discovery by Nirenberg and Matthaei of cell-free protein synthesis in response to synthetic ribonucleotide polymers opened up any hopeful-looking avenues towards its solution. Now, Lanni's bibliography runs to about 400 titles, of which approximately 85 per cent are dated 1960 or later. This is in fact one of the big break-through salients on the biological front. The question that arises is: can any biologist not personally engaged in this particular foray find the time to follow, blow for blow, the course of the engagement? Moreover, will those who are engaged in it find here anything they did not know already? The immediate tactical situation is altering so rapidly that there are certainly some things which they will not find. For example, anyone who attended the recent Royal Society Mendel Centenary Celebrations in London will have heard Brenner argue that there must be a DNA codon for chain termination. I spent about half an hour looking for a reference to this in Lanni's article and failed to find it.

The next article is by D. H. Davidson on differentiation in monolayer tissue culture cells. This is again a fashionable field but of a rather different kind. There has been no major theoretical break-through. It has been known for a very long time that cells in tissue culture tend "to lose their differentiation". Davidson's review contains at least 500 references, but of the 100 which I sampled, at least 60 were published before 1960 and as many as 50 before 1950, quite a number of them going back before 1930. His article, in fact, gives a convincingly inclusive review of the present state of a complex and slowly advancing field.

The other two articles are of a quite different kind, both being devoted to authoritative summaries of specialized investigations in circumscribed fields. Verne Grant gives an account of the studies that have been made of a group of sibling species in the genus *Gilia*—small herbaceous plants common in western North America and South America. This is a valuable addition to the general body of knowledge about plant evolution. Oelkers summarizes the results of species crosses in the plant genus *Streptocarpus*, in which there have been many tantalizing indications of the importance of cytoplasmic factors. Our understanding of at least some types of cytoplasmic inheritance is being so rapidly advanced by studies on more genetically amenable forms, such as those of Sager on *Ochlomyxdomonas*, that we are now faced with the challenge of passing well beyond the mere recognition of the existence of cytoplasmic factors; but this seems to be all that we can expect from the study of the more recalcitrant higher plants.

In sum, the new volume of *Advances in Genetics* well earns its place on the shelf of any well-stocked library. The first article will be extremely useful to a few people

for a short time before it becomes out of date. The last three will be valuable to perhaps fewer people at any one time, but for a longer period. C. H. WADDINGTON

## TETRAPYRROLE BIOSYNTHETICS

### Tetrapyrrole Biosynthesis and Its Regulation

By Dr. June Lascelles. (Microbial and Molecular Biology Series.) Pp. xii+132. (New York and Amsterdam: W. A. Benjamin, Inc., 1964.) 7.70 dollars.

DR. JUNE LASCELLES has made important contributions over the past ten years to our knowledge of the synthesis of porphyrins and bacteriochlorophyll in photosynthetic micro-organisms and, in particular, of the factors concerned with the regulation of this process.

The most important part of *Tetrapyrrole Biosynthesis and Its Regulation* is a critical and informative discussion of the control of this chain of reactions. However, this discussion, which forms chapter five of the book, is preceded by an account of the main structural features of tetrapyrroles, their physical properties and the methods used for the isolation and identification of both porphyrins and chlorophylls. A second chapter deals in a somewhat brief but concise manner with the distribution of haemoglobins in animal tissues. Dr. Lascelles considers, in more detail, the presence of the haemoglobins and especially of cytochromes in micro-organisms and in strictly anaerobic bacteria. She describes in a helpful manner the work which has been done, chiefly in the past few years, on the occurrence and probable function of the various cytochromes present in photosynthetic organelles and organisms.

Another section deals with the accumulation of porphyrins in micro-organisms, both of the photosynthetic and non-photosynthetic type; here it is of special interest that in most of these organisms it is coproporphyrin III which is present in relatively large amounts. A third chapter deals with the biosynthesis of tetrapyrroles, but this subject has been covered recently in a number of reviews. However, special emphasis is given here to work in micro-organisms, and the relationship between the biosynthesis of porphyrins and the more general metabolic reactions in the cell is emphasized.

Dr. Lascelles then deals with the chain of reactions leading from protoporphyrin to chlorophyll or bacteriochlorophyll. Many steps in this reaction sequence have been established, but there are many more for which no detailed information is available and for which enzymes have so far only been postulated. The structure of the chloroplast and that of the chromatophore is discussed in detail, and the important finding, which was mainly established by Dr. Lascelles and her colleagues, that the synthesis of bacteriochlorophyll and of protein is closely related, is rightly emphasized. However, as has already been stated, the most important part of the book is undoubtedly the chapter dealing with the control mechanisms, and this topic can be more easily investigated in micro-organisms than in animals.

The effect of light and oxygen tension has been known for some time, mainly due to the work of van Niel. Dr. Lascelles has herself contributed much to our understanding of the role of iron and she has also shown the repression of ALA synthetase by small amounts of haemin. Amino-laevulinic acid itself appears to repress ALA synthetase, but it is likely that other reactions may also play a part in the overall regulation. Thus we still know very little about the availability of glycine or of succinyl co-enzyme A or the importance of the methylation step in the overall regulation of the biosynthesis of chlorophylls by the cell.

There is obviously much more work to be done in this field, but the book by Dr. Lascelles not only reviews the present position fully but is also likely to stimulate many readers to do further investigations in this important field. A. NEUBERGER

## BIOLOGICAL ORGANIZATION

### Homeostasis and Feedback Mechanisms

Edited by G. M. Hughes. (Symposia of the Society for Experimental Biology, No. 18.) Pp. viii+460. (Cambridge: At the University Press, 1964. Published for the Company of Biologists on behalf of the Society for Experimental Biology.) 70s. net.

PREVIOUS symposia of the Society for Experimental Biology have covered a wide range of topics which fall within, between or across the accepted subdivisions of the science of life, and it has been clearly established that no aspect of biology is beyond the Society's terms of reference. This eighteenth symposium on *Homeostasis and Feedback Mechanisms* is concerned with every aspect of biological organization from subcellular to ecological levels, and beyond, and we are soon reminded that organismal homeostasis is only possible within quite small limits of change in the physical environment. Both the aqueous and gaseous environments in which life is found are themselves maintained in remarkably stable states of dynamic equilibrium which, though still little understood, are essential for life as we know it.

To encompass a theme of such wide biological application, it was necessary to choose between attempting a comprehensive but somewhat superficial coverage, or to seek a more profound understanding at a number of representative points. By tradition, and perhaps also by judgment, the latter course was followed, but at the risk that only the few or the very few would grasp fully the meaning of every contribution. Generally speaking, the editor has succeeded, and this whole series of wide-ranging papers is both pertinent and comprehensible.

There are twenty papers in the volume. After a brief discussion of homeostasis and the environment (Pantin), there are treatises on behavioural and physiological adaptation to both desert (Bartholomew) and arctic (Hart) conditions; on the control of temperature in man (Benzinger), respiration in fishes (Hughes), salt balance in crustaceans (Shaw) and growth in insects (Wigglesworth), while others consider the special adaptations in diving vertebrates (Anderson), the control of mammalian metabolism (Randle), the homeostatic significance of the hypothalamus (Cross) and of the adrenal cortex (Chester-Jones and Bellamy). Papers on genetic aspects of homeostasis (Robertson) and of circadian rhythms (Harker) complete the representation of biological systems in which the processes of control have been investigated.

There is not, because there cannot be, any sharp division between the presentation of experimental and theoretical aspects of biological control processes, but the latter part of the volume becomes increasingly concerned with the application of physical concepts to the study of these processes. Some biologists may feel somewhat humbled by the paper on the use of statistical mechanics in a theoretical approach to cellular organization (Goodwin), but subsequent contributors help to restore self-confidence. The discussion on the concept of feedback mechanisms in mental processes (Frank) is followed by a fascinating analysis of the wing control of insects (Weis-Fogh), of orientation control in flies, birds and man (Mittelstaedt) and of position sense and effort sense in man (Merton). In the paper on the techniques of system-analysis applied to feedback pathways in the control of eye movement (Fender), we are reminded of the need of the biologist to consider this whole subject of the application of control theory at some depth if he is to begin to understand the processes of physiological control: "... simple devices of linear feedback are not sufficient; we need the whole armamentarium of non-linear analysis, adaptive controls and sampled-data theory if we are to make any appreciable headway with the problem—it may be that new forms of mathematics must be developed especially to deal with the complexities of biological

problems". In the final paper (Machin) the whole complex subject of feedback theory is drawn together in about as near as one can hope to get to plain words.

A brief historical introduction to the theme of the symposium might have been included. Neither Virchow, who showed an early appreciation of the importance of the organizational levels of biological material, nor Claude Bernard, who gave birth to the concept of internal regulatory mechanisms of living material, is mentioned. But omissions were inevitable. When 'homeostasis' is in danger of being taken for granted, and 'feedback' has become a piece of popular jargon, this volume deserves high commendation as a brave effort to provide biologists with a faithful and readable guide to the level at which their thoughts must be projected when they seek to consider or express the processes of life in the language of the engineer, or to analyse them with the aid of his mathematical tools. It is also a reminder of the limitations of such expressions. The most complex machines yet devised are but simple things compared with the integrated functions of even a single cell. The engineer's concepts and formulae may be adequate for the construction of simple analogies, but may not serve to describe the processes of living organisms for many aeons.

This pleasantly laid-out and well-produced volume is not a handbook, and not every student of biology will read it with relish or absorb its contents with ease, but it is a thought-provoking introduction to a subject of increasing interest and importance and deserves wide attention.

J. BLIGH

## DEADLY PRAIRIE PLANTS

### Poisonous Plants of the United States and Canada

By Prof. John M. Kingsbury. (Prentice-Hall Biological Science Series.) Pp. xiii+626. (Englewood Cliffs, N.J., and London: Prentice-Hall, Inc., 1964.) 78s.

INFORMATION on specific poisonous plants is commonly required by workers in a number of disciplines. Frequently, however, such information is difficult to extract from the literature and even then may not be first-hand. A service in respect of both these deficiencies is provided in *Poisonous Plants of the United States and Canada*, a comprehensive but not exhaustive survey of the relevant literature marked by a successful attempt to "identify original sources of information for the reader". A well-chosen and extensive bibliography allows access to more detailed material.

As a prologue there is a compact and useful synopsis of the literature on poisonous plants up to 1900, accompanied by its own set of references. The next section deals with poisonous principles. This is necessary in order to treat certain groups such as alkaloids, various types of glycosides and some inorganic salts in a general manner so that the monographs are not repeatedly interrupted to describe properties common to all the members of each group. In our present state of knowledge, this must have been the most difficult chapter to write. Systematization is difficult as a chemical classification tends to overlap and, where the chemistry is still uncertain, terms in common use are often descriptive rather than scientific. In the circumstances the account is straightforward and comprehensible. There are some useful charts—of basic configurations of alkaloids and poisonous plants which contain them, of plants with cyanogenetic potential, of plants in which toxic concentrations of 'nitrates' have been found and of plants which may accumulate selenium. Other sub-sections deal with goitrogenic substances of botanical origin and plants causing photosensitization. There is a short but lucid account of the cardiac glycosides.

The main body of the book is arranged on a botanical classification and consists of a series of monographs interspersed with subsidiary information on related genera

and species. Each monograph is essentially divided into botanical data (description, distribution and habitat) for identification of the plant source and toxicological data (poisonous principles, toxicity, symptoms and lesions, and conditions of poisoning) for recognition of the effects produced. This design makes it most useful to the veterinarian and physician for the detection of plant poisoning. The author is aware that the bias is veterinary rather than human but, quite rightly, argues that this is "a true reflection of emphasis in the literature". The physician will nevertheless find much that is of interest, as also will the botanist, pathologist and pharmacologist. The monographs are well presented, provide accurate information and are suitably annotated. References to plant poisoning occurring outside North America are introduced, where relevant, with profit. The illustrations are clear and well placed in relation to the text; the few colour photographs make one wish that they were not so costly and could be used more extensively. The treatment of plant poisoning is not the concern of this book, though some specific antidotes are mentioned.

This is an excellent book. The author throughout strikes a good balance between essential facts and trivial, albeit interesting, information. His style is easy to read and his presentation shows a wide understanding of the subject. The book is well produced and typographical errors are minimal. Here are a few trifling criticisms. The formula of hypericin (page 173) is unnecessary as it has already been given on page 54. Coniine (page 381) and lobeline (page 392) are piperidine rather than pyridine derivatives. It is not clearly stated that atropine (pages 277, 280 and 282) is racemic hyoscyamine, does not occur naturally and is produced by racemisation during the processes of drug extraction. The titles of two formulae are incorrect, 5-vinyl-2-thioxazolidone (page 27) and mimosine (page 332) which should end "alpha-amino-propionic acid". None of this detracts from the enjoyment of reading this most valuable and interesting work. H. F. GRUNDY

## NUCLEAR PROPULSION AND POWER IN SPACE

### Nuclear Energy in Space

By Erik S. Pedersen. (Prentice-Hall Space Technology Series.) Pp. xi + 516. (Englewood Cliffs, N.J., and London: Prentice-Hall, 1964.) 160s.

"THIS book attempts to mould the various topics (of nuclear energy in space) together and, at the same time, cover each of them in great detail with theories, equations, pictures, tables and practical examples." So says Dr. E. S. Pedersen in his introduction to *Nuclear Energy in Space*. This, in itself, is a prodigious task, but also to include a wide range of peripheral subject-matter makes it all the more formidable.

The book opens with a brief account of the history of nuclear energy and a survey of nuclear aerospace programmes in the United States. The second chapter lays down some of the more basic satellite theory, deriving basic equations for propulsion nozzle design, the relation between mass ratio and burnout velocity for a rocket, the dynamics of injection into orbit and orbital theory. Finally, possible trajectories for Moon and Mars landings are considered, with some reference to rocket staging and the use of nuclear rockets. The foundation of the basic theory continues in Chapter 3, with a treatment of heat transfer and fluid flow, with particular reference to reactor cooling. Equations for heat transfer by conduction and forced convection are derived and empirical results presented. The theory is used to derive expressions for the transfer of heat into a fluid flowing in a pipe with axial symmetry and to show how the heat transfer characteristics play an important part in determining reactor

size and operating pressures. Chapter 4 discusses the principles of fission with particular reference to  $^{235}\text{U}$ , defining the basic parameters, such as cross-section, and outlining the way the fission processes may be controlled in reactors. Methods of reactor analysis are mentioned. The foundations of the basic knowledge required for nuclear rocket design are completed in Chapter 5 with a catalogue of a considerable number of structural, heat-resistant, moderator, shielding and other materials, giving their mechanical and a few chemical properties and including their resistance to radiation.

Chapter 6 is devoted to the design of a nuclear rocket engine; nozzle design is reconsidered, giving more attention to detail, and some theory is given for optimizing nozzle mass. Some of the problems of engine start-up and shut-down are described and the system dynamics are worked out for the design of a nuclear rocket giving expressions for the time constants of the reactor and turbo machinery: a block diagram for a possible control system is given. Finally, the chapter deals with a specific reactor design and some of the results are given of the calculations to determine power and temperature distributions for a 60-MW reactor.

Consideration is given in Chapter 7 to 'advanced propulsion methods'. These seem to be systems which are primarily in the research stage and include liquid fuel reactors for use with venturi nozzles, thermo-nuclear and photon propulsion, electric propulsion and a form of nuclear propulsion where it is proposed to explode small nuclear bombs ( $\sim 0.01$  kton) about 1,000 ft. behind a spacecraft: propellant emanates from the bomb and "propagates . . . to the vehicle where it hits a pusher plate that propels the vehicle".

Considerable attention is devoted, in Chapter 8, to direct conversion of energy into electricity. Thermo-electric and thermionic conversion are discussed with theory and sketches, and fuel cells, chemical batteries and solar cells are alluded to more briefly. Details are given of the SNAP series of power supplies, with both reactor and isotopic energy generation. The STAR systems are also mentioned.

Chapter 9 discusses the effects of the explosion of nuclear devices both in and above the atmosphere. It describes the effects of the release of vast quantities of energy, the blast, the thermal and nuclear radiations, and gives the energy yield of fission and fusion reactions. The discussion is accompanied by graphs and calculations.

The final chapter gives a brief account of the types of nuclear radiation encountered in space, their flux and energy; and describes the effect of radiation on man and on the components of satellites. Finally, shielding methods are described, including the possibility of using magnetic fields for charged particle deflection.

To write a comprehensive book on such a disjointed subject as nuclear engineering is not easy, to say the least. It is scarcely surprising, therefore, that one which also includes many additional topics seems to be a series of almost unrelated papers rather than a complete entity. While this does not detract from the value of the book as a wealth of information, it does make the information more difficult to extract.

With regard to notation, efforts have clearly been made to conform with accepted practice but sometimes this has led to confusion; for example, the symbol ' $n$ ' appears in the nomenclature for Chapter 8 as a number of fragments/sec, while in that same chapter it is also used for number of thermoelectric couples per module, and in the same calculation as total number of thermoelectric couples. In this particular case the latter two ' $n$ 's differ by a factor of 10, thus misleading an unwary reader. The use of several systems of units in the book causes little difficulty because of the admirable set of conversion factors the author has included. Even a viscosity expressed in one chapter in lb.<sub>m</sub>/ft. hr. can readily be converted into the more humble poise.

This book represents a considerable achievement. It has knitted together every conceivable application of nuclear energy in space and will be of enormous help, particularly to those who are just embarking in this field, but also to the student and established space engineer. Priced at 160s., it will probably not adorn many private shelves, but, considering that it contains enough material to fill several more modest books, the price would not seem unreasonable.

B. P. DAY

## CULT AND CULTURE

### The Temple and the House

By Lord Raglan. Pp. xi+218. (London: Routledge and Kegan Paul, 1964.) 30s. net.

THE recent death of Lord Raglan robbed ethnology of one of its most penetrating and independent minds. His work, however, has still, one feels, to be given the attention and esteem it merits. This comparative neglect he shares with A. M. Hocart, surely one of the most brilliant of British cultural anthropologists, whose friend he was, whose literary executor he became and with whose general standpoint in social studies he agreed. The central theory underlying their work is that ritual, a term under which they subsumed all the phenomena variously classified elsewhere as magical or religious, forms the seed ground of civilization; that, in tracing back to their origins features of contemporary cultures, even those which now and for some time have had purely secular and commonplace roles, we arrive at a matrix which is a fusion of cult and culture. This thesis is enormously powerful and fruitful, but obviously finds resistance in minds attuned by the ruling influences of our existing intellectual climate to thinking about human activities as pre-eminently representing an adaptation to needs, biologically or psychologically defined, and, consequently, finding plausible explanations of human cultural characteristics couched in functional, naturalistic or economic terms and dominated by the widely accepted concept of 'adjustment'. Hocart's work was concentrated mainly in the field of social organization. He produced in *Kingship and Kings and Councilors* a great weight of evidence in support of the idea that in a neolithic and pre-neolithic ritual matrix are found theocratic forms of society and government which, by diffusion from a few centres, have been greatly influential in shaping the social forms of peoples over large parts of the world. Raglan's work was supplementary to this and dovetails with it.

In *The Temple and the House*, his last work, Raglan argues that the house, far from being as with us a purely secular building, a close approximation in these days to "a machine to live in", has in a great many cultures a whole series of characteristics which attest to its sacredness; that, even in the modern West, there still remain associated with the house a number of practices which are explicable only as survivals of this same sanctity. The house is, or has been, the locus of the cult of domestic gods and deified ancestors. Indications that its site has been divinely chosen are sought before proceeding with a ritual demarcation which will establish it as a sacred island in a secular world. Sacrifice forms part of the foundation of house walls or pillars, and further sacrifices are required after completion of the structure and before occupation. The threshold, as leading to a divine abode and as itself the abode of a number of protecting deities, remains especially sacred: precautions have to be taken in crossing it, especially by a bride newly consecrated by a marriage ceremony that has made her a house mistress with a number of distinctly priestly attributes. The sanctity of the dwelling, henceforth pre-eminently in her charge, is even more clearly seen in a whole series of specifications for its preservation, for keeping it free from ritual pollution. It is impossible on utilitarian grounds to

account for these—for the taboos on cooking in the house, on childbirth, on raising children, on death in the house. They derive rather from a religious complex, the central notion of which was that the cosmos had originally emerged from a preceding undifferentiated potentiality—the 'Chaos' of Genesis—through the operation of a constructive dualistic principle that resulted in a world of paired entities and attributes, complementary but in tension, a world of sky and earth, land and water, right and left, good and evil, light and dark, life and death. This belief was taken so seriously that it gave rise to a prolonged series of endeavours to build the world of man's own making—his culture—on the same foundational principle, and this work was marked by a most extraordinary scope and consistency. The central rite associated with this doctrine was the marriage of sky and earth represented first by selected individuals who later developed into the divine king and queen. The generative, or regenerative, efficacy of this ritual union required its location in a building which symbolized the cosmos and which formed the prototype of palace, tomb and temple. These, in consequence, reflected in their shape and design the dominating cosmographic ideas; at first round or spherical, they later became square, their corners carefully orientated with the "Earth's imagin'd corners". The history of the house shows, apart from emulation, the control of the same notions, for it too was sacred because it was the dwelling of a man and wife consecrated by a sacramental union derived from the sacred marriage, a derivation made plain by the widespread treatment of bride and groom as queen and king and by the cosmic associations of their marriage bed.

The book presents its thesis and its supporting evidence with Raglan's customary economy of exposition and an engagingly succinct but sufficient rebuttal, *en route*, of various alternative explanations. It opens the gate on a very rich field. Questions of cultural origins are patently difficult, but a continuing enquiry into them, guided by the evidence, not by our preconceptions, is necessary. We would thus safeguard ourselves against the 'ennui' and trivialization that frequently attend social studies out off by a too functionalist approach from history and from that discovery of meaning which is a discovery of beginnings.

BRYNMOB THOMAS

## PROGRESS IN PETROLEUM CHEMISTRY AND REFINING

### Advances in Petroleum Chemistry and Refining

Vol. 9. Edited by John J. McKetta, jun. Pp. xv+439. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1964.) 150s.

IN 1958 a literary project was inaugurated with the ambitious objective of presenting in book form, at annual intervals, progress reports by leading authorities in the fast-growing disciplines of petroleum chemistry and refining. It was initially argued, with some justification, that: "The industry is so diversified that men in one phase have little knowledge of the progress made in other segments. The research scientist does not know what the engineer is accomplishing, nor does the engineer know what may come from the basic research of the scientist". To the extent that this dictum is sound, the appearance of the ninth consecutive volume of the rather expensive *Advances in Petroleum Chemistry and Refining* would seem ample justification. The only doubt in my mind is to what extent can the 'pure' petroleum chemist and the chemical engineer concerned with oil refining speak a common language, and thus understand the intricacies of the complex researches on which each is engaged? When one considers that oil refining, as originally understood, no longer consists of processing crude oil for fuels and

lubricants and end-products, but now embraces complex chemical processes in the industrial fields of fertilizers, petrochemicals, plastics, rubber, to name only a few branches, then this question would appear to have some substance in fact.

The problem is by no means resolved by appeal to the titles of the eight contributions contained in the present volume. These are: "Advances in Large-scale Oxygen Production", by R. L. Shaner and L. C. Matsch; "Hydrodealkylation", by G. F. Asselin; "Formulation and Structure of Lubricating Greases", by B. W. Hotten; "Thermal Cracking and Pure Saturated Hydrocarbons", by B. M. Fabuss, J. O. Smith and C. N. Satterfield; "The New Elastomers", by W. W. Crouch and R. S. Hammer; "Mechanisms of Carbonium Ion, Carbene and Carbanion Reactions", by G. M. Cramer and T. J. Wallace; "Synthetic Ammonia", by S. Strelzoff and L. C. Pan; "The Chemistry of Fuel Instability", by T. J. Wallace. A glance at the cumulative index of the specialized subjects dealt with in the nine volumes published so far spreads the net very wide indeed, but this presumably was the purpose of the series in the first place.

The series as yet does not add up to a text-book which the student can read to learn more of his chosen subject. Neither is it a cohesive dictionary of either petroleum chemistry or refining. It is, in fact, a reference series written by specialists for specialists and, as such, a valuable source of information on many subjects to those who wish to keep abreast of modern developments in the sciences and technologies wherein their main interests lie. Refresher courses in the sciences in which professional men and others have long since qualified are constantly in the minds of practising chemists and chemical engineers; those engaged in the petroleum industry, including its widest ramifications, are by no means behind members of other faculties in their recognition of the importance of revitalizing their work, but time and circumstances do not always permit such seminars. This series of volumes does, within obvious limitations, at least provide a useful means of leisure-study in the specialized subjects so far treated; to this extent it undoubtedly fills a gap in contemporary technical literature of scientific progress of petroleum technology which future volumes may well gradually narrow.

H. B. MILLER

## ADVANCES IN CHEMICAL ENGINEERING

### Advances in Chemical Engineering

Vol. 5. Edited by Thomas B. Drew, John W. Hoopes, jun., Theodore Vermeulen and Giles R. Cokelet. Pp. x+317. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 100s.

THE five topics in Volume 5 of the Academic Press series, *Advances in Chemical Engineering*, are all processes involving reaction kinetics or transport processes. Each represents a valuable contribution to the literature in the field concerned. Three of the authors are American, one is British and the fifth is Dutch.

The first article, on flame processes, by J. F. Wehner, is an excellent review of the fields of combustion and detonation. The author has approached the subject by acquainting the reader with the general theories of flame processes and shows how some useful approximations can be made to the equations for mass and heat balances within a flame. Experimental techniques for measuring temperature and concentration profiles are discussed and the importance of a prior knowledge of the magnitude of the reaction rates is emphasized. This is illustrated by investigating the probable chemical stages in the combustion of methane and showing the difficulties of estimating the concentration profiles of all the molecular species present. The hydrodynamic stab-

ility of stationary and propagation flames is approached with special reference to ignition and quenching. The transition from the laminar combustion wave to the shock wave is discussed in terms of the hydrodynamic conditions preceding the detonation. The burning of solid propellants is shown to be a particularly difficult problem because of the intermediate mixing problems involved. The article concludes with the possible applications of flame processes in chemical engineering. The flame is regarded as a form of chemical reactor from which normally short-lived molecular species might be isolated by quenching. An interesting possibility is the condensation of finely divided solid particles from flames.

The use of bifunctional catalysts which are discussed in the second article, by J. H. Sinfelt, represents an important application of heterogeneous catalysis within the chemical industry. These materials have been developed during the past ten years, particularly in petroleum refining, and there are now many opportunities for their more extended use. In the article, the general principles of functioning of such catalysts and the nature of the reactions occurring have been described. Hydrogenation and isomerization are taken as illustrative examples. Some of the outstanding problems to be solved before the catalysts can be widely used have not been presented, however. Thus, heat and mass transfer receive a rather perfunctory treatment even though they may be determining factors. Methods of preparation of bifunctional catalysts could well have been discussed in this article, particularly whether it is advantageous to include two components in the same catalyst pellet.

Heat conduction or diffusion with change of phase is the subject of the article by S. G. Bankoff. A number of diffusional processes, with both constant and variable diffusion coefficients, are discussed, and it is concluded that the subject is well developed in cases where the boundary conditions are simple. There are, however, many problems involving, for example, the melting of solids or the condensation of material on nuclei where the phase boundary is continually moving. Analytical solutions are given to a number of problems and numerical methods are also developed. On the whole the article would have been improved by a clearer statement of the physical problems presented and by a less piecemeal approach.

The article on flow of liquids in thin films by G. D. Fulford is a useful review of the hydrodynamics of such systems. There does not appear to have been a previous review of this important field, but the long list of references shows the amount of work carried out in recent years. The author is to be commended on providing a list, at the end of his review, giving a brief résumé of each of the major contributions in the field. The only criticism is that the treatment of the mechanical energy equations for unsteady systems is inadequate.

The volume concludes with an article by K. Rietema on segregation in liquid-liquid dispersions and its effect on chemical reactions. He reviews the concepts of flow patterns in reactors suggested initially by Danckwerts and then goes on to examine the effect of segregation on conversion rate for reactions of various orders. The effects of limitation due to mass transfer are considered with reactions proceeding both in the continuous and disperse phases. In many cases the behaviour of a process is difficult to interpret because of a lack of basic knowledge of the kinetics of the reaction in question. In stirred vessels, the effect of dead corners at baffles and the effect of increase in mean drop size with distance from the stirrer are examined. This article is particularly useful, as the field is one attracting an increasing number of investigations at present.

The volume is attractively produced, in the same style as its predecessors. It is, overall, a work of a high standard, but is expensive for its length.

J. F. RICHARDSON

### The International Zoo Yearbook

Vol. 5. Edited by Caroline Jarvis. Pp. ix+430+72 plates. (London: The Zoological Society of London, 1965.) 105s. net.

**THE International Zoo Yearbook** has already shown itself to be indispensable, and the publication is clearly going from strength to strength. The 1965 volume, edited as before by Caroline Jarvis, with the help of a strong advisory committee, exceeds that of 1964 by nearly 100 pages and includes more than 80 photographic plates and a large number of text illustrations. The reference section follows the accustomed lines and provides ready information about the technical developments and various lines of progress at the zoos and aquaria of the world during the past twelve months. This section alone makes it indispensable to directors of zoos and their staffs. In addition to this purely factual data, Section 2, comprising 150 pages, deals with new developments in the zoo world. The sub-headings of this section include "Breeding" (17 separate articles, contributed by 19 authors); "Stock" (25 articles by 30 authors); together with smaller groups of papers on "Aquarium Management"; "Veterinary Work"; "Zoological Research"; "Educational Activities"; and "Architecture and Construction". The veterinary papers range from accounts of new surgical operations and new hypnotic and anaesthetic agents for birds and fish, to tooth trimming in vicious lions and "false teeth for an old donkey".

In each issue of the *Yearbook*, it has also become customary to include one or two special features. Last year we had a symposium on aquatic mammals in captivity and a survey of animal milk analyses and hand-rearing techniques. This year the special emphasis is on "Ungulates in Captivity"—the whole of Section 1 (90 pages) being devoted to this subject. Conservation is again an important topic in the form of the report of the symposium on "Zoos and Conservation", held in 1964 at the London Zoo. A valuable section, arranged more or less after the manner of the zoological record, entitled "Veterinary Work and Zoological Research Undertaken at Zoos and Aquaria in 1963", is an important innovation in this volume.

Finally, there is a closely-printed 10-page section describing new buildings in zoos and aquaria during 1963-64. It is a sobering thought that this includes 30 zoos which are either entirely new or so extensively reconstructed or extended as to be virtually new. With this extraordinary development in the increase of interest in animals, and the desire to see them in captivity throughout the world, we must emphasize again the imperative need for world-wide and effective control of capture, transport, export and import, of the rarer wild animals. If this is not done, and done thoroughly, the demands of the world zoos could easily outstrip supply (indeed, they are already doing so), leading to many cases of extermination among those species which cannot as yet be readily bred in captivity.

W. H. THORPE

### The Action of Neuroleptic Drugs

A Psychiatric, Neurologic and Pharmacological Investigation. By Prof. Hans-J. Haase and Paul A. J. Janssen. Pp. viii+174. (Amsterdam: North Holland Publishing Company, 1965.) 40s.

**THE** drugs which are used in the treatment of psychiatric disorders produce a wide variety of effects. *The Action of Neuroleptic Drugs* is an attempt to define the psychic and somatic actions of the major tranquillizing or neuroleptic drugs. Part 1 of the monograph, by Prof. Hans-J. Haase, describes the neuroleptic effect and shows how this came to be regarded by him as a reduction of extrapyramidal conation. This interpretation is illustrated by the author's clinical observations. Several neuroleptic drugs are compared with chlorpromazine with

regard to dosage and equivalence of therapeutic effect and some subjective observations on the effect of neuroleptic drugs are given. Prof. Haase has found that fine motor extrapyramidal signs are associated with the neuroleptic effect and can be used as an indicator of this effect. He describes how handwriting tests can be used to observe the degree of fine motor hypokinesia which occurs and gives several illustrations. It is thought that most of the coarse motor extrapyramidal disturbances, which can occur when these drugs are used, are not related directly to the neuroleptic effect. Chapter 3 gives details of clinical schemes for the investigation of the neuroleptic action of drugs. This is followed by a review of the therapeutically undesirable effects of neuroleptic drugs, contributed by J. Wagensommer.

The final part of the book, by P. A. J. Janssen, is a short pharmacology of neuroleptic drugs. These can be divided into three main groups: the drugs which are structurally related to reserpine; the derivatives of phenothiazine and their isosteric compounds; and the drugs derived from butyrophenone. The neuroleptic, anti-emetic and adrenolytic activities of thirty-six drugs, as determined in tests on laboratory animals, are compared. The book contains much information about this group of drugs, but its use as a source of reference is limited by the absence of an index. It is, however, relatively cheap, and worth reading, and will no doubt stimulate further investigations into the action of neuroleptic drugs.

D. F. SHARMAN

Survey of the Limba People of Northern Sierra Leone By R. H. Finnegan. (Department of Technical Co-operation. Overseas Research Publication, No. 8.) Pp. 151. (London: H.M.S.O., 1965.) 25s. net.

**PRIOR** to the research of Miss Ruth Finnegan (now Mrs. Ruth Murray, of the University of Ibadan) the Limba people of the northern province of Sierra Leone had never been the object of anthropological investigation. This modest and useful book seeks primarily to provide basic information about political structure, social institutions, economy, religion and migratory labour. One of its virtues is the way the author has attended to what the Limba say about their own society and to its distinctive features, instead of trying to present the material in the categories found useful in one of the more celebrated investigations of some other African people.

A Limba chief is expected to be continually accessible to his people, from whom he is not separated by intermediary officials. Traditionally, his fundamental task has been to reconcile litigants and "cool their hearts". The setting up of the 'Native Authority' system of administration—useful as a check on unprogressive and autocratic chiefs—has, among the Limba, robbed chiefship of its traditional justification by establishing independent courts. At the same time, the chief, being a salaried official, no longer needs to cultivate the confidence of his people. Literate chiefs find the office 'boring' and now tend to look towards a career outside the chieftdom. Economic development is affecting many institutions—a man is no longer dependent on his kinsfolk to raise bride-price for his wife, and a woman who dislikes her husband may earn enough to repay this sum herself—but traditional ideas of shame, witchcraft, ownership, etc., remain important to any understanding of the contemporary position. The book concludes with a chapter showing that in spite of the new sense of economic individualism, many of the incentives to labour migration are still founded in the traditional Limba order. The farming year is still, for the Limba, an absorbing and God-given cycle; their work, disputes, ceremonies and entertainments are enjoyed with pride and skill. The peasant workers may sometimes be tired or hungry, but they, at least, are never bored.

MICHAEL BANTON

## TIME'S ARROW AND ENTROPY

By Sir KARL POPPER

University of London

SEVERAL years ago<sup>1</sup> I suggested that we should distinguish between two essentially different ways in which energy can be degraded or dissipated: "Dissipation in the form of increasing disorder (entropy increase) is one of them, and dissipation by expansion without increase of disorder is the other. For an increase of disorder, walls of some kind are essential: a sufficiently thin gas expanding in a 'vessel without walls' (that is, the universe) does not increase its disorder." Reasons for this view were given in the place cited.

In order to explain this a little more precisely, I shall here introduce, following Prigogine<sup>2</sup>, the term 'system' to denote the (energy and material) "contents of a well-defined geometrical volume of macroscopic dimensions" (so that, for example, an organism enclosed by its skin, or our solar system as enclosed by a sphere round the Sun with a radius of  $10^4$  light seconds, would be a 'system'); and I shall speak of the 'exterior' of a system  $X$  as a region of space (leaving it open whether or not this is in its turn a geometrically well-defined 'system') of which  $X$  forms a part.

Following Prigogine, I shall distinguish between (materially or at least energetically) 'open' and 'closed' systems. (An energetically closed system is called 'isolated'.) Moreover, I shall call a system  $X$  'essentially open' if it is part of a system  $Y$  such that all geometrically convex systems of which  $Y$  is a part are (at least energetically) open. (This definition makes it possible even for an isolated system to be essentially open.)

I further call  $X$  'essentially open towards a cooler exterior' if  $X$  is enclosed by some convex system  $Y$  such that: (a) all elements of any sequence  $Z_i$  of convex systems of which  $Y$  is a part are essentially open and of a lower average temperature than  $Y$ , and that (b) for every such system  $Z_i$  there is a system  $Z_j$  which encloses  $Z_i$  and which is not of a higher average temperature than  $Z_i$ .

The terminology here introduced makes it possible to clarify a number of points in connexion with the second law of thermodynamics which seem in urgent need of clarification.

Again following Prigogine<sup>2</sup>, we can split the change of entropy  $dS_X$  in any system  $X$  into two parts:  $dS_{X_e}$ , or the flow of entropy due to interaction with the exterior of  $X$ , and  $dS_{X_i}$ , the contribution to the change of entropy due to changes inside the system  $X$ . We have, of course:

$$dS_X = dS_{X_e} + dS_{X_i} \quad (1)$$

and we can express the second law by:

$$dS_{X_i} \geq 0 \quad (2)$$

For an energetically closed (or 'isolated') system  $X$ , for which by definition  $dS_{X_e} = 0$ , expression (2) formulates the classical statement that entropy never decreases. But if  $X$  is open towards a cooler exterior:

$$dS_{X_e} < 0 \quad (3)$$

holds, and the question whether its total entropy increases or decreases depends, of course, on both its entropy production  $dS_{X_i}$  and its entropy loss  $dS_{X_e}$ .

The fact that entropy can decrease in an open system  $X$  does not, of course, conflict with the second law as given by expression (2). But the second law is often formulated in a different way; for example, it is said that "if we . . . expand our system to include all the energy exchange, it would be found that in the larger system the entropy had increased. For example, to measure the entropy change

taking place in living organisms as a whole, it would be necessary to include in our system the Sun and some additional portion of the universe, as well as the Earth itself"<sup>4</sup>. Thus it is suggested that for sufficiently large systems  $X$  of our universe,  $dS_X \geq 0$ , so that the entropy always increases.

Yet, so far as our knowledge of the Universe goes, the precise opposite appears to be the case. With very few and short-lived exceptions, the entropy in almost all known regions (of sufficient size) of our universe either remains constant or decreases, although energy is dissipated (by escaping from the system in question). This is so, at any rate, if we assume that the law of conservation of energy is valid; and it is also so if we assume the 'steady state' theory of the expanding universe. (It is not so on the assumption of a finite and non-expanding universe with non-zero energy density.)

In order to see this, all that is needed is to be clear about the empirical fact that in our universe we know only essentially open systems, and only systems  $X$  which, so far as they produce entropy at all, are essentially open towards a cooler exterior. (This is true even of all so-called 'closed' or 'isolated' systems.) But for all such systems, one of the following cases must hold: (a) they are (practically) stationary, like the solar system and most stars known to us, in which case their entropy production (practically) equals their entropy loss, at least temporarily; or (b) they are losing temperature, and thereby entropy; or (c) they are producing more entropy than they lose, in which case they are in process of getting hotter, a process which, whether energy conservation is assumed or the steady state theory, can be only a comparatively rare and short-lived temporary process. (Even if the system in question should be one that collects matter from its environment until its gravitational field becomes so strong as to encapsulate and separate off the system from the rest of the universe, it would thereby presumably become stationary.) All we know about the universe points to (a) and (b) as being by far the most frequent and important cases: in almost all sufficiently large systems known to us, entropy production seems to be equalled, or even exceeded, by entropy loss through heat radiation.

This may be explained by the conjecture that every entropy-producing region is open towards some large (perhaps infinite) sinks of energy—regions the energy capacity or heat capacity of which, at least for heat in the form of radiation, is infinite (or approximately so for all practical purposes). The existence of such sinks seems to be strongly indicated by the darkness of the night sky. (We might represent this conjecture by the model of an infinite universe with zero energy density; or by that of an energy-conserving expanding—and therefore cooling and entropy-destroying—universe which tends towards zero energy density; or by that of an expanding steady-state universe with constant temperature, and entropy production equalled by entropy escape.)

So there do not seem to be theoretical or empirical reasons to attribute to expression (2) any cosmic significance or to connect 'time's arrow' with that expression; especially since the equality sign in expression (2) may hold for almost all cosmical regions (and especially for regions empty of matter). Moreover, we have good reason to interpret expression (2) as a statistical law; while the 'arrow' of time, or the 'flow' of time, does not seem to be of a stochastic character: nothing suggests that it is subject to statistical fluctuation, or connected with a law of large numbers.

As for the evolution of life, this seems to be connected, if at all, with a cooling rather than a heating process on Earth (or perhaps with periodic temperature fluctuations); that is, with increasing order and decreasing entropy. Yet it does not seem that 'feeding on neg-entropy' has much to do with the preservation of life, as has been suggested, for example, by Schroedinger<sup>4</sup>. For during the incubation of birds' eggs entropy rather than neg-entropy is supplied to them, though they are in a period of increasing organization; and while in an organism dying of heat

or of fever entropy may increase, if it dies of cold—say, by deep-freezing—its entropy certainly decreases.

## THE OFFICE FOR SCIENTIFIC AND TECHNICAL INFORMATION

By DR. H. T. HOOKWAY

Government Department of Education and Science, Curzon Street, London

BRITISH scientists and technologists are becoming increasingly aware of the rapid growth in the amount of scientific and technical information which is becoming available for dissemination and retrieval. The impact of this so-called 'information explosion' varies from subject to subject, and there are corresponding differences in the attitudes of individual scientists to it. But common to all is the realization that the problem of handling information will become steadily worse as the years go by and that it must be tackled effectively before it gets out of hand.

A new Office for Scientific and Technical Information (OSTI) has been set up within the Department of Education and Science to promote more activity on information problems and to co-ordinate the work of the various interested bodies. It is being built round a nucleus of staff transferred from the Department of Scientific and Industrial Research (DSIR), which was giving increasing attention to information problems during its last years. The functions of OSTI have been made very wide so that within the resources at its command it may stimulate or, if necessary, undertake almost any activity that can contribute to a better handling or utilization of information in both the natural and social sciences and their related technologies.

### Research

It has become clear in recent years that the problem of handling information by machine methods is much more difficult than was once thought. The application of computers to information problems has raised tantalizing possibilities—of mechanical translation, of storing whole texts on magnetic tape and of retrieving information selectively in packages of convenient size—but experience has shown that these goals cannot be reached by computer technology alone. It is necessary to conduct more fundamental research into the nature of the language in which scientific information is expressed, in order that satisfactory means can be found of manipulating data and ideas by machine with the minimum of human intervention. Thus, for example, machine translation cannot progress far beyond its present crude achievements until much more is understood about the grammar and semantics of language. Mechanical analysis of stored abstracts or texts for retrieval purposes can only be of limited value until more is understood about the linguistic and psychological relationships between indexing terms.

This is complex, long-term, multi-disciplinary research of a kind which does not easily attract research workers in its early days. Until recently the bulk of this work has been carried out in the United States, but teams now exist in the U.S.S.R. and several West European countries. In Great Britain the National Physical Laboratory has three such research projects within the programme of its Autonomics Division, and OSTI has taken over from

the DSIR support of five projects in the field of structural linguistics, each involving collaboration between linguists, computer specialists and mathematicians, and five more projects which in one way or another are aimed directly at better retrieval of information. One project in this second group, in the University of Sheffield, forms part of a planned British contribution to the vast programme of research and development at Chemical Abstracts Service.

### Development of New Techniques and Systems

It is impossible, of course, to foresee if and when research of this kind will lead to a radical solution of the information problem and, if so, how widely applicable the solution will be. Therefore, since much of research is long-term in character, a proportion of total resources must be devoted to the development and application of ideas that already exist, because some of them show promise of being better than, and as acceptable as, existing methods which they would supplement or replace. The bulk of these ideas fall into the category of reference retrieval systems; that is to say, they store titles and bibliographical citations on magnetic tape which can then be used for: (1) general publication; (2) selective dissemination to individuals or groups; (3) retrieval; or (4) a combination of these applications. The other approaches concern not bibliographical information but selected quantitative data, which can be more easily handled by machine than information expressed in words.

In the United States much thought is being given to the possibility of establishing a mechanized information service for each scientific discipline and for each major area of application—space, atomic energy, medicine, agriculture and engineering. In general the American institutions concerned recognize their problem as an international problem and are prepared—in many instances keen—to co-operate with institutions outside the United States that have something positive to offer. From the outset, then, OSTI has accepted the need for co-operation with the United States, and indeed with other countries, and to help international organizations to promote co-operation, where possible, on an even wider basis.

**Medicine.** The character and state of development work vary from one subject to another, and the nature of British participation must vary accordingly. At one extreme, in medicine, a mechanized search service known as 'MEDLARS' (Medical Literature Analysis and Retrieval Service) has existed in the United States since July 1964. Run by the National Library of Medicine, it enables the announcement journal *Index Medicus* to be printed by computer-controlled type-setting and provides a facility for machine searching of the indexed material that has already been put into the system. The National Library of Medicine is prepared to supply copies of the MEDLARS tapes to organizations in other countries which will provide national searching services for medical literature on the

lines of those already provided in the United States, and OSTI has launched a project for the establishment of a MEDLARS 'station' in Britain. It has placed a three-year contract with the Computing Laboratory of the University of Newcastle upon Tyne for the preparation of the necessary search programmes and the experimental operation of the service; and the National Lending Library for Science and Technology (for which OSTI is now responsible) has acquired the necessary expertise in search strategy and will back up the search service with the supply of literature.

I must emphasize that any new service such as this will be experimental at first. Inherent in the project is a programme of tests designed to indicate the potential value of the service to the medical profession and the pharmaceutical and related industries and to evaluate the indexing procedures used. The result of these tests will determine whether the service is worth establishing on a permanent basis and should be of use in the design of similar systems for other subject areas.

**Engineering.** In engineering the situation is rather different. The Engineers Joint Council, a body which brings together the main engineering institutions in the United States and has close ties with the abstracts publication *Engineering Index*, has produced an elaborate thesaurus of major engineering terms, which it hopes will become the basis of a mechanized bibliographical service. It has also been promoting experiments in the selective publication of abstracts taken from *Engineering Index*, the first two subject areas being plastics engineering and electrical/electronics engineering. In Great Britain the Institution of Electrical Engineers has been experimenting with new journals of a different kind—a list of current titles, which has already established itself, and a letters journal; while the new National Electronics Research Council, with support from OSTI, has embarked on a preliminary design study for a project concerned with the evaluation of a mechanized system for selective dissemination of information to electronics research workers. This Council is already discussing co-operation with the Engineers Joint Council (EJC) on the development of the EJC thesaurus as part of the design study, and this, it is hoped, will be only the first stage in a period of fruitful co-operation.

**Chemistry.** Although there are chemical thesauri which could be used as the basis of a chemical information service, interest in this field centres on the massive research and development programme of Chemical Abstracts Service (CAS), which is now supported by several American Government agencies. The aim of this programme is to develop a mechanized information service based on the structures of known compounds, and it is hoped that eventually the system will be able to handle information on physical and chemical properties and applications associated with particular structures. As I have said earlier, a contribution is already being made from Britain on the research side, and the Chemical Society, in consultation with OSTI, is working out plans for a British contribution to the CAS programme involving both long-term research and the testing of new services as they are developed, in order to relate these services as closely as possible to the needs of chemists.

**Physics.** This subject is of particular interest in Britain because responsibility for the major English-language abstracting system lies here. Recent discussions have brought the two British organisations concerned—the Institution of Electrical Engineers and the Institute of Physics and the Physical Society—into close relationship with the American Institute of Physics, and together they are working out a programme of research and development affecting both *Physics Abstracts* and *Electrical Engineering Abstracts*. It will be one of OSTI's functions to ensure that this work is fully co-ordinated with related work elsewhere, including work that OSTI is already supporting at the National Electronics Research Council.

### Critical Data

There is a quickly growing recognition that the task of data compilation, for too long left to enthusiastic individuals or groups, now needs proper stimulation and co-ordination. The U.S. National Bureau of Standards has launched a large National Standard Reference Data Program designed to identify and fill gaps and to ensure a uniformly good quality of output. The International Council of Scientific Unions has recently considered how best this problem, like many others in the information field, can be tackled on an international basis, and it is encouraging the individual unions to consider what is being done in their own subjects and what further work might be stimulated.

It is clear that Britain must mobilize her own contribution to the total effort and must consider, with other interested countries, how the growing quantity of data should be organized for ease of use. An *ad hoc* committee, with representatives of the Royal Society of London and DSIR (before its dissolution) as well as independent scientists, has compiled a short list of subject areas in which a clear British interest already exists and the total British effort could be stimulated; and OSTI is now supporting, or about to support, three 'urgent' items on this list. It is also considering what experiments should be made in Britain with specialized data centres, combining a measurement service for scientists, and perhaps research on methods of measurement, with the collection, evaluation, extrapolation, dissemination and retrieval of data. A feature of such centres would be the development and use of mechanized handling methods.

### Other Activities

The promotion of research, development and data compilation will be the frontier-pushing activities of OSTI. There are, however, two other important tasks which will demand increasing attention—help to existing information organizations to improve their services and stimulation of educational activities.

**Existing services.** It is not possible to say much about the future development of existing services at this early stage in the history of OSTI. However, the past decade has been one of considerable growth and experiment, with the establishment of the National Lending Library for Science and Technology, the preparatory work on a National Reference Library for Science and Invention, the expansion of Aalib's activities with the help of a large grant from DSIR (now from OSTI), the extension of specialized services in research associations and elsewhere, and the strengthening of personal liaison services both in the research associations and through the network of industrial liaison officers based on technical colleges—a network financed by the Ministry of Technology and the education departments.

At the same time the place of each type of organization in the total information system is the subject of much interest and investigation. For example, the University Grants Committee is examining the arrangements for meeting the needs of university libraries, while the Department of Education and Science is setting up two Library Advisory Councils (for England and Wales) under the Public Libraries and Museums Act, 1964. The Library Association has been examining the problems of library services in general and has recently published proposals for a national bibliographical service. The Ministry of Technology is giving urgent attention to developments in industrial information services that may secure more rapid application of science in industry. Aalib has been re-examining its research programme with a view to accumulating useful knowledge on modern information systems and techniques and offering an efficient technical service to members on information problems. It will be OSTI's task to bring together these various growing points and see how far the ideas that are

emerging can best be fused into a national policy for the development of scientific library and information services. It will also promote new services wherever they are proved to be necessary. But it will not seek to run such services itself unless no other suitable organisation exists inside or outside the Government.

**Education.** So far as educational work is concerned, OSTI will try to accomplish two fundamental tasks—systematic training for information work and systematic education of scientists and engineers in the use of literature and information services.

The increasing volume of scientific and technical information is leading to the establishment of more information departments and special libraries. Consequently more staff are required to operate them, and it is important that employers should be able to recruit a sufficient number with appropriate training. However, until recently there were no academic courses for information scientists. Information officers could receive no formal training except in library schools, which cover only part of the field, however, and so had to do much of their learning 'on the job' with the valuable help of short specialized courses run by the Association of Special Libraries and Information Bureaux and other bodies.

The first attempt to provide systematic training was a part-time course in information science which was started at the Northampton College of Advanced Technology, in 1962, mainly for scientists already engaged on information work. This proved popular, and was supplemented in the following year by a full-time postgraduate course. In October 1964 a full-time course for graduates in science and technology was started in the Postgraduate School of Librarianship in the University of Sheffield. Both these full-time courses have been accepted by the Science Research Council for the tenure of its studentships. OSTI is about to launch a national survey of the employment of information officers, hoping to discover, among other things, the distribution of officers in different kinds of work and the likely demand for trained officers in years to come. The results should help to determine the scale and character of training provision that are required. In addition OSTI is anxious to encourage research training in order to relieve the present acute shortages of both teachers for the training programme and research workers for the kind of research projects which I have described earlier.

Systematic education in the use of scientific literature and information services is so important to the success

of research, development and application that it seems incredible that so few scientists and engineers have received formal training in the use of information and that so many remain unable to make effective use of it throughout their working life. However, the National Lending Library, which as I said earlier is administered by OSTI, has in recent years been experimenting with short courses for postgraduate research students, university and academic staffs and library school tutors with the object of arousing interest in providing this sort of instruction as part of the normal university and college training. The response to these courses has been very encouraging and some universities and colleges are now providing such instruction themselves. But much more needs to be done, and OSTI, through the National Lending Library, intends to give it all possible encouragement.

### Conclusion

This description of OSTI's field of interest should be sufficient to show that the new organization has a difficult and complex task to perform. In addition to promoting a wide range of activities, it must endeavour to co-ordinate the efforts of all kinds of organisations—Government and independent—and to link these efforts with what is happening in other countries and in international organizations. Indeed, co-ordination should be regarded as perhaps the most important part of OSTI's total function.

The creation of OSTI has been widely recognized as timely, and it starts life with a large number of well-wishers. How successful it will be must depend to a large extent on its resources—human and financial. For the present financial year it has been allocated the sum of £180,000 for grants and contracts—considerably more than was available to DSIR for this work in former years. But I must emphasize the fact that it would be very easy to allocate the entire sum to worth-while projects which are already under discussion. We shall have, therefore, to exercise great care in the selection of priorities. Staffing is likely to present more serious problems, because relatively few scientists and technologists have both interest in the subject and the administrative capacity which is necessary for promotional and co-ordinating work of this kind. The period of recruitment, which starts this summer, will thus be crucial to the long-term success of OSTI.

## CIBA IN BRITAIN

### NEW FUNDAMENTAL RESEARCH UNIT AT HORSHAM

CIBA's new Horsham fundamental research unit was opened on May 12 by His Excellency M. Béat de Fischer, the Swiss Ambassador, and an inaugural address was given by Lord Snow, Parliamentary Secretary of the Ministry of Technology. The new £250,000 unit consolidates the Company's pharmaceutical research plans which first took shape in Great Britain in 1939. During the Second World War, CIBA Laboratories, Ltd., supplied drugs to the armed Services, hospitals and medical practitioners, despite shortage of staff and materials. The subsequent growth of the Company's business has been such that to-day sales are twenty times as great as they were in 1946.

In 1962, CIBA decided to establish the fundamental research division at Horsham, adjoining the existing laboratories, for long-term research study of drug action with emphasis on biochemical pharmacology—how drugs achieve their effect in the body. This was a concrete expression of the Company's appreciation that in recent

years the whole field of biochemistry has opened up at an accelerating pace. As the total knowledge derived from research all over the world has increased, even greater precision has to be applied in the testing of medications. With techniques for gauging the action and reaction of chemicals in the body becoming more and more accurate, the pharmacologist to-day aims towards more precise, and therefore safer, drug effects.

Work on drugs in human medicine will be paralleled in the veterinary field, in which CIBA has already contributed several therapeutic advances.

CIBA has an experimental farm at Monks Gate (four miles south of Horsham), and, as its work develops, collaboration with the new research unit on biochemical problems is envisaged.

Present techniques help research scientists to find the answers to such questions as how drugs are distributed through the body, drug metabolism (changes which may occur in a drug through the body's enzyme action) and

A multi-volume work . . .

**THE FUNGI** *An Advanced Treatise* edited by **G. C. Ainsworth** and **A. S. Sussman**

This treatise is designed to provide a critical and modern survey of a group of fungal organisms that are important to basic and applied biology. The first complete review of the biology of the fungi to be written in this century, the editors have synthesized the writing of noted international scientists who are currently working in this field.

Directions for future research are highlighted, along with discussion of the present status of knowledge of the fungi. Information on the fungi from the fields of biochemistry, genetics, physiology, cytology, ecology and evolution is critically evaluated and incorporated within the framework of this treatise.

**BIOMEDICAL TELEMETRY** edited by **C. A. Caceres**

This volume is intended to provide an integrated account of the state-of-art in telemetry as it affects medical and biological applications in both research and routine practice. The book will prove useful to engineers, biologists, and physicians who are concerned with planning systems for research or for investigative studies of physiologic signals, and who face problems of monitoring patients and subjects.

(C050) September 1965, 382 pp., 120s.

**LIGNIN BIOCHEMISTRY** by **Walter J. Schubert**

This monograph is concerned with two fundamental aspects of the lignin problem: the enzymic mechanism of its biogenesis in living, lignifying plants, and the mechanisms which nature has provided for the gradual removal of the synthesized lignin of non-living plant material, such as by the enzymic activities of microorganisms. These biochemical considerations are made more meaningful by projection against an outline of pertinent fundamental aspects of the chemistry of lignin. A brief review of earlier work on aromatic biosynthesis in microorganisms is also included.

Sections include:

- Introduction: The Chemistry of Lignin
- Aromatization in Microorganisms
- Biogenesis of Lignin in Higher Plants
- The Microbiological Degradation of Lignin

(S140) August 1965, 131 pp., 64s.

**THE KJELDAHL METHOD FOR ORGANIC NITROGEN** by **R. B. Bradstreet**

This monograph is a comprehensive survey of the Kjeldahl method for organic nitrogen and its modifications as applied to natural products and organic materials. Included is a bibliography of published papers covering the entire period from the inception of the method.

**CONTENTS:** INTRODUCTION TO THE KJELDAHL METHOD: Text References. THE KJELDAHL DIGESTION: Acid Requirements. Decomposition of Organic Material. Salt Addition. Miscellaneous Salts. Oxidizing Agents. The Boiling Period after Digestion. Reducing Agents. Catalysis. References. DIGESTION PROCEDURE: Natural Products. Organic Materials. Submicro Methods. DISTILLATION AND DETERMINATION OF NITROGEN: Text. References. BIBLIOGRAPHY OF THE KJELDAHL METHOD FOR ORGANIC NITROGEN. Author Index.

(B692) Fall 1965, about 250 pp., 76s.

In two volumes . . .

**HANDBOOK OF PREPARATIVE INORGANIC CHEMISTRY, Second Edition** edited by **Georg Brauer**

Translated by Scripta Technica, Inc.

Translation edited by Paul G. Stecher

Special experimental methods, techniques, and apparatus are presented together with detailed methods for preparation of inorganic compounds. For all substances described, controllable and reproducible preparative conditions are given—all have been verified by laboratory experience. Important individual methods found throughout the book are linked to the main techniques given in the first section.

(B714) Volume 1, 1963, 1002 pp., 257s. 6d.

## Bacterial Colony Counter

- Suitable for pathogenic and non-pathogenic bacteria.
- Fast counting with all transistor circuit.
- 4 inch magnifier for viewing colonies.
- Counting by either reflected or transmitted lighting.
- Designed for both left- and right-handed use.

so on. Knowledge of the action of a drug on cellular metabolic pathways may also help research scientists to envisage possible undesirable long-term side-effects.

These, and many other investigations, are the subjects of research in the new unit, which is equipped with some of the most modern and comprehensive facilities in Great Britain. The main working laboratories are housed on the first floor of the new building and comprise three biochemical, one isotope, two pharmacological and two analytical laboratories. The latter constitute the analytical department, which assesses the purity of all products which are produced at Horsham and also provides consultative and collaborative facilities for the research workers. Here, too, are the chromatography room, the optical instrument room and a balance room.

The ground floor houses such general-purpose sections as special accommodation for the animals used in research, a mechanic's workshop, a centrifuge room, glass-washing and cold rooms, large-scale laboratory and a flame and flood-proof room for hazardous experiments. There are photographic facilities and a library which contains more than ninety scientific journals and several hundred reference works.

The equipment reflects the complexity and cost of biological research to-day. There are radiometer autotitrators and gas chromatography equipment for analysis, an Associated Electrical Industries EM6B electron microscope specially designed for biological work such as examining changes in cellular structure under the influence of drugs with a magnification of 250,000, a scintillation counter for isotope measurement, a preparative ultracentrifuge with a rotor speed of 50,000 r.p.m., a polygraph recorder for pharmaceutical work, self-recording spectrophotometers and a spectrophotofluorimeter.

Work of the kind carried out at Horsham is slow and painstaking. Although modern research is a team endeavour, progress is still made by the individual research scientist, who must be backed up by skilled assistants and resources. The Horsham research team of ten graduate scientists—who work under the overall direction of Dr. D. F. Elliott, head of the research unit—have such support in the persons of thirty technicians and ancillary staff, for the most part locally recruited.

Close liaison is also maintained with the Clinical Research Division and the CIBA research laboratories in Switzerland and the United States, from where selected compounds are sent to be investigated at Horsham. Constant exchanges of ideas, too, are made with academic and clinical institutions and similar bodies in Great Britain.

CIBA (Chemical Industry in Basle) was formed in Basle, Switzerland, in 1884. To-day, it comprises 58 associated companies throughout the world, employing more than 28,000 people. In Great Britain itself there are seven associated companies, of which CIBA Laboratories at Horsham manufacture and sell ethical pharmaceuticals and agrochemical products; CIBA Chemicals, Ltd., at Grimsby, which manufactures bulk pharmaceuticals and chemicals; the Clayton Analine Co., Ltd., in Manchester, which manufactures dyestuffs; CIBA Clayton, Ltd., also in Manchester, which sells dyestuffs, pigments, and textile application products (finishing agents used in textiles, plastics and many other industries); and CIBA (A.R.L.), Ltd., and Bonded Structures, Ltd., both at Duxford, which manufacture and sell synthetic resins and adhesives and deal with their application in construction materials. The holding company in London is CIBA United Kingdom, Ltd.

Through CIBA's international research programmes, the Company is able to make available to the National Health Service drugs which have been significant advances in many fields of medicine. After earlier contributions in the fields of anaesthetics, stimulants and sedatives have come major new developments in treating cardiovascular disease, especially hypertension. The broad fields of dermatology and allergy have benefited from several CIBA drugs, as have much more specialized problems such as iron-poisoning and the diagnosis of rare conditions.

CIBA also believes that pharmaceutical research should be international. Research is at present being carried out not only at the Company's headquarters in Basle, but also at CIBA Corporation, Summit's establishment in New Jersey, United States, and also at the CIBA of India, Ltd., Goregaon Research Centre.

#### Agrochemical and Veterinary Developments

**Veterinary.** Although the veterinary surgeon has been using CIBA medical products for many years, it was not until 1959 that the first CIBA preparation was fully tested in veterinary medicine. Since then, a large staff of veterinary surgeons has been built up at the three chief centres of CIBA's veterinary activity, that is, Switzerland, the United States and Great Britain.

The large-scale research with many types of drugs enabled CIBA to market several new compounds for the veterinary surgeon. The Company's work over many years in the field of corticosteroids allowed it to introduce 'Vecortenol' (prednisolone trimethylacetate), the

Fig. 1. New CIBA fundamental research unit at Horsham

Fig. 2. Base works of CIBA, headquarters of the organization.

longest-acting corticosteroid available in veterinary medicine. Other corticosteroids such as hydrocortisone were marketed in dermatological preparations.

CIBA was one of the first companies to manufacture sulphonamide preparations, and many new sulphonamides have come from the CIBA research laboratories. Three such compounds not previously seen in Great Britain have all been marketed exclusively for veterinary medicine.

The Company's experience of diuretics has enabled Horsham to introduce the first non-toxic injectable diuretic for veterinary medicine, and it has given the veterinary surgeon the first antihistamine with a stimulant action. CIBA is rapidly building up an interesting range of veterinary specialties.

**Agricultural.** In the course of research conducted by CIBA, the problem of chlorine utilization provided the impetus for research in pesticides. The substantial amount of chlorine produced as a by-product at the organization's Monthey plant was turned to use in the manufacture of copper oxychloride, then replacing the traditional Bordeaux mixture as a protectant fungicide.

The development of pesticides and their formulations, and of detergents, also had an important prerequisite in the scientific experience gained in textile application products and plastics. Similarly, experience gained in the pharmaceutical field gave a knowledge of bactericidal agents.

It was with this background that CIBA started its agricultural activities. When, in 1963, Horsham entered the field, it was with a dairy detergent/sterilizer that sales activities were first started. This was quickly followed by the introduction of a new selective herbicide, mainly used to kill weeds on strawberry beds. Since then other products have been developed for such diverse uses as the control of insects in glasshouses, and for the prevention and control of scour in calves and pigs.

Of prime importance in the development of both agricultural and veterinary products is the work of the CIBA Farm near Horsham, which was in fact purchased and in operation on research projects by 1960. This farm works in close co-operation with other CIBA research stations all over the world in developing and investigating both new and existing chemicals for use in connexion with agriculture and veterinary medicine.

### AIMS AND OBJECTIVES OF CIBA

During his speech at the opening of the New CIBA fundamental research unit at Horsham, Dr. Robert Kappeli, chairman of the board of directors, stressed that it was an international company. That does not merely mean that it manufactures and sells its products in many different parts of the world. CIBA as a living organization has taken root in the soil of many countries, and flourishing offshoots have grown up round the parent tree. Each of these affiliates is native to the country where it operates, and shares its fortunes. The British Company is an example. After small beginnings in a London office, it moved—still small—to Horsham shortly before the outbreak of war in 1939. During the war years some of its members served in the Armed Forces, and the others maintained the output of essential drugs under very difficult conditions.

When the post-war expansion came, CIBA, Horsham, also grew—in the volume of business, the size of its establishment, and in the number of its personnel.

From the very beginning down to the present day the Company has always had British personnel—from the senior management down to the youngest recruit. At the same time CIBA, Horsham, is part of a world-wide organization. This means that it shares in the wealth of scientific experience and industrial knowledge accumulated over a period of many decades, and in many parts of the globe.

However, the main centre of CIBA research is in Basel, Switzerland (Fig. 2), where a new pharmacological building equipped with the most modern facilities is being erected at a cost of about six and a half million pounds. This figure may serve to indicate the importance which is attached to research—and also the burden which it imposes on the industry.

The Horsham research unit is, of course, much smaller in size than that in Basel. However, with its strong accent on biochemistry, it will make a very important contribution to CIBA's research effort. One looks forward to a lively exchange of ideas and experience between the Horsham Research Division and its counterparts in Switzerland, the United States and India (in the last-mentioned a modern research centre at Goregaon, near Bombay, has recently been established).

A great deal more might be said about the importance of international co-operation in industrial pharmaceutical

research as it is practised in an organization like CIBA, and also about the fruitful interchange which goes on daily between academic and industrial research laboratories.

It is an established fact that many, if not the majority, of the most effective therapeutic agents available to-day for the treatment of bacterial infections, hypertension, diabetes and many other formerly intractable diseases could not have been developed and made available at reasonable cost and in abundant quantity without the pharmaceutical industry. Yet, Dr. Käppeli claims, this industry is at the present time and in many countries the object of the most violent attacks and accusations of profiteering and reckless exploitation. The cry for increased supervision, Government control, and even for nationalization is constantly being raised. In view of the indisputably substantial contributions of the pharmaceutical industry to the health and well-being of the individual and the community at large, this attitude seems highly illogical. How is it to be explained?

The *Journal of the Royal Society of Arts* of October 1963 and *Nature* (200, 441; 1963) printed the text of the Truman Wood Lecture, delivered by Prof. Ernst Chain, entitled "Academic and Industrial Contributions to Drug Research". In his lecture Prof. Chain, a Nobel Laureate and a biochemist of world-wide reputation, pays eloquent tribute to the co-operation between academic and industrial research, and gives a large number of examples, drawn from many fields of clinical medicine, which demonstrate the important part played by the research-minded industry in the development of new drugs. It would be impossible to overstate the importance of this Lecture as an impartial appraisal of a situation which is in danger of being completely clouded by sentiment and ignorance of the facts. Nobody unfamiliar with the development of drug research during the past half-century should attempt to pass an opinion on the merits or shortcomings of the pharmaceutical industry without having read Prof. Chain's lecture very carefully.

It is not necessary here to list the many examples given by Prof. Chain to demonstrate the value of co-operation between academic and industrial research. Yet attention

should be directed to some of Prof. Chain's remarks on the place which the pharmaceutical industry holds in the world to-day and on the effect which any tampering with its basic structure would be likely to have. He says: "The layman must understand that the pharmaceutical industry is life-saving and as such fulfils a public function of very great importance. Let it be clearly understood that I refer here, of course, only to those industrial organizations which are actively concerned in drug research and production. This type of industry is essentially productive, and not parasitic in nature, and is one of the most positive assets to our form of society".

Prof. Chain thus makes a clear distinction between firms which engage in research and those which merely thrive on the labours of others. This is a distinction which is highly important. All the leading companies of the industry maintain large research laboratories at great cost in money and manpower, because it is certain that without them progress would be impossible. Then come the copyists, who are domiciled in countries where the law allows them to operate with impunity. They seize on substances developed by others at great cost and often after years of laborious research, manufacture them at little expense beyond the bare production costs, and offer them for sale at cut-throat prices, sometimes even with the active support of Government authorities. Immediately, the Company which developed the original product is branded as a profiteer and an exploiter of the public, and soon the cry for control or nationalization of the drug industry is raised.

It is a commonplace which scarcely bears repeating that virtually all the progress in the development of new drugs during recent years has been in those countries where the principle of free enterprise still operates. The reason for this is not far to seek: the development of a new drug, to say nothing of breaking ground in an entirely new direction of research, is a highly speculative venture requiring very large sums of money and a willingness to take the calculated risk that all the effort and expenditure may yield no tangible result. Except possibly in war-time, these pre-requisites to success are not usually found in State-owned organizations.

## ROYAL BOTANIC GARDENS, KEW

### NEW JODRELL LABORATORY

By DR. C. R. METCALFE

Keeper

ON May 7, Lord Florey, president of the Royal Society of London, opened the new Jodrell Laboratory at Kew. The ceremony was attended by the Minister of Agriculture and other distinguished guests.

This bald statement of fact covers an event of very great significance in the history of the Royal Botanic Gardens, Kew, as a centre for botanical research. The new building (Fig. 1) stands on the same site as the modest laboratory, some 40 ft. long by 20 ft. wide, which was presented to Kew by Mr. T. J. Phillips Jodrell and opened in 1876. It is well known to botanists that, despite its small size and unassuming appearance, the old laboratory was the scene of many classical investigations such as Dukinfield Henry Scott's work on coal measure plants, and the work by Horace T. Brown and F. Escombe on the diffusion of gases through minute, closely crowded holes in plates of celluloid so fashioned as to resemble stomata in the surfaces of leaves. Then, again, there was the work on plant diseases by George Massee, which led ultimately to the opening of a small plant pathological laboratory on Kew Green, where the work in due course expanded into the present-day activities of the Commonwealth Myco-

logical Institute and the Ministry of Agriculture's Laboratory of Plant Pathology at Harpenden. We can thus see that these two important departments are, historically speaking, 'descendants' from the old Jodrell Laboratory. In the old building we can also picture Arthur W. Hill (who later became director of Kew) and Walter Gardiner studying the continuity of protoplasm, F. O. Bower working at Pteridophytes, W. C. Worsdell studying plant anatomy and teratology, all of which investigations were, in their day, of first-class importance. Later on we think of L. A. Boodle and F. E. Fritsch translating Solereder's *Systematic Anatomy of the Dicotyledons* into English, and of Boodle with his well-known care and caution establishing the botanical identity of a great number of archaeological specimens from Ancient Egypt, notably those from the now world-famous tomb of Tutankhamen.

These events, important as they are in the history of British botany, belong to the past and we may well ask ourselves why Kew now requires a new laboratory, what sort of accommodation and equipment it contains and for what purposes it will be used. In considering these

matters it must first be remembered that although many kinds of work are undertaken at Kew the foremost importance of the institution is as a centre for the study of plant classification. Furthermore, there are more species of living plants in cultivation at Kew than elsewhere and these have been assembled from many different parts of the world. Bearing these facts in mind, we must go on to recall that plant classification, while still based primarily on the external characters of plants, which are the special concern of herbarium workers, has now reached a stage where very little further progress in taxonomy can be achieved without the aid of ancillary investigations relating to the histology and cytology of the plants concerned. Indeed, we are now also approaching an era in which a knowledge of the chemistry of plants (chemotaxonomy) seems destined to assume a more important taxonomic role.

For some years the anatomists at Kew have been engaged in producing a series of reference books on systematic anatomy, volumes which are now widely used throughout the botanical world. It must clearly be a first duty to continue this work. But this fundamental work on systematic anatomy must be supplemented by further, more detailed, histological work and by parallel studies concerning the cytology of plants in relation to their classification. Karyological investigations not only produce additional taxonomic characters, but also deepen our knowledge of breeding mechanisms and so help us to understand the interrelationships of closely related species and to lay bare the probable course of their immediate past evolution. Besides all this, the successful cultivation of so many living species from so many diverse localities within the 300 acres of Kew poses many physiological problems that are scarcely likely to come to the notice of physiologists at other centres in Britain. Seeds are sometimes hard to germinate, cuttings are difficult to strike, other species can be kept alive successfully but will not flower, and there are the still more difficult problems presented by species which cannot at present be maintained in cultivation at all. With the passage of time the old Jodrell Laboratory became inadequate to enable us to deal with all these subjects, and the accommodation and equipment were insufficient.

With this background in mind, it was a great day for Kew when the members of the visiting group under the chairmanship of Sir Eric Ashby recommended that one of

our most pressing needs was an up-to-date laboratory to enable us to face the challenge of modern developments.

The research work in the new Jodrell Laboratory will be conducted in three departments concerned with (i) morphology and anatomy, (ii) cytology, and (iii) physiology, respectively. This division of subjects is, however, somewhat artificial and has been adopted only as a matter of administrative convenience. It is clearly evident that many of our problems will call for collaboration between specialists in each of the departments. The really important point is that specialists in all these subjects will be working together in the same building where they can help each other.

In these days of extreme specialization it is becoming increasingly important to maintain an adequate sense of perspective and to review the aims and objects that we have in mind when we undertake our investigations. There is always a danger that a specialized branch of research may become fashionable and be continued for that very reason rather than because of its intrinsic merits. In viewing the research prospects of the new Jodrell Laboratory we must remember that it has come into being in an age of almost unparalleled changes throughout the world. These changes are bound to have an impact on our botanical work. In particular, air travel is opening up possibilities that were not previously available to us. As we travel over deserts, oceans, mountain ranges and the dense forests of the tropics, we are reminded, for example, that only a small proportion of the world's species have been examined under the microscope; that soil erosion is active in many regions, and unless we press on with our task of microscopical examination there is a danger that many species will have become extinct before we have even taken a really close look at them. Meanwhile, in our universities the interests of botanical students are largely determined by the relative mark-earning values of different disciplines. Among these a knowledge of the world's vegetation and of the sheer diversity of form exhibited by the plants of which it is composed does not appear to rank very high. There is, therefore, a danger that modern students will not be taught to view the excitements of ultra-structure against the broad background of the tropical forest. This lack of sense of perspective can lead to a wrong sense of values and we may even forget what botany is all about. It is, therefore,

Fig. 1. The new Jodrell Laboratory at the Royal Botanic Gardens, Kew.

particularly appropriate that there is a widespread hope that the opening of the new Jodrell Laboratory will mark the beginning of an era of closer co-operation between Kew and the universities, a form of symbiosis which could, in favourable circumstances, be of great mutual advantage to all concerned. The incorporation in the new laboratory of a fine, modern lecture theatre, with accommodation for audiences of up to 200, should also facilitate collaboration between Kew and the universities, since it will provide an appropriate setting for meetings of learned societies as well as for groups of students. It will also enable our many visiting research workers, who come from all over the world, to make the nature of their investigations more widely known. The lecture theatre will also provide more adequate opportunities to make the scientific work of Kew more widely known among the general public.

It would be wrong to conclude this article without referring to the fact that the new building contains two much-needed teaching laboratories, intended primarily for

giving instruction to our student gardeners. To meet the occasion, the training scheme for these young people is being revised and modernized. If all goes well they should indeed be fortunate, for there can be few students who have both horticulturists and botanists of high standing as their mentors and are at the same time privileged to work in the midst of the wealth of living plants that are in cultivation at Kew.

In conclusion, it may be said that the new Jodrell Laboratory is a well-balanced unit that will serve alike as a research centre and for teaching and discussion, and which will also provide a means of communication between Kew and other botanical institutions as well as with the general public. The staff inherit a strong tradition for hard work and tenacity of purpose. They have better facilities and equipment than their predecessors and, if these are rightly used, there is every expectation that our knowledge of plant life will be both widened and deepened. The new Jodrell Laboratory provides both a challenge and a wonderful opportunity.

## NEWS and VIEWS

### Universities Federation for Animal Welfare:

Major C. W. Hume, O.B.E.

THE retirement of Major Hume from the post of secretary-general of the Universities Federation for Animal Welfare ends nearly forty years service on behalf of the welfare of animals, especially those used in laboratory experiments. He graduated in physics at Birkbeck College, and then joined the Patents Office, becoming senior examiner. He was editor to the Physical Society during 1919-40, and as honorary secretary of the British Science Guild organized the campaign which resulted in the Patents Act, 1932. He served in the Royal Engineers (Signal Service) during the First World War and afterwards in the 47th Divisional Signals (Territorial Army). During the Second World War he also served in the headquarters staff for Army Operational Research, and took part in various work in connexion with Signals Development. Hume will be remembered especially, however, for his life-long devotion to the welfare of animals. He was the founder in 1926 of the University of London Animal Welfare Society (ULAWS), followed in 1939 by the Universities Federation for Animal Welfare (UFAW). In addition to the administration of these organizations, first as honorary secretary and later as secretary-general, he has taken a very active part in the promotion of many Bills concerning the welfare of animals. His publications include *The Status of Animals in the Christian Religion* (1926), *Man and Beast* (1962), and numerous articles on animal welfare, statistical analysis, the strategy and tactics of experimentation, patent law, rabbit control, and other topics.

### Metallurgy in the University College of Swansea:

Prof. H. O'Neill

In September 1964, when he retired, Prof. H. O'Neill concluded a period of seventeen years at the University College of Swansea as head of the Department of Metallurgy. Thus he concluded a professional career which, commencing in 1920, has embraced all aspects of metallurgy. Hugh O'Neill was born at Sheffield in 1899 and, after two years National Service in the First World War, graduated with honours in the University of Sheffield. The next fourteen years were spent in teaching metallurgy, and during this period he published his well-known book, *The Hardness of Metals and its Measurement*. In 1929 he was awarded a D.Sc. degree by the University of Manchester. In 1935 he resigned his post as senior

lecturer in the University of Manchester and joined the Research Department of the London, Midland and Scottish Railway at Derby, where he served as chief metallurgist until 1947. During this period he was much concerned with welding and helped to initiate the Abington Research Station. His publications ranged from bearing metals to the welding of steels and the study of rails, and the paper on this last subject to the Institution of Civil Engineers was awarded the Trevithick Premium. After his appointment as professor of metallurgy at Swansea, he continued research on the deformation and hardness of metals, including transformation effects in electrodeposited alloys and deformed austenite and, in 1950, a Nuffield travelling fellowship enabled him to visit metallurgical plants in Canada and the United States. Prof. O'Neill has been a member of council of the British Iron and Steel Research Association, a visitor for the Department of Scientific and Industrial Research and an honorary member of council of the Iron and Steel Institute. A founder member of the Institution of Metallurgists, he was elected president in 1952. In 1961 he was elected president of the Institute of Metals. Other activities have included presidency of the Newman Association and chairmanship of the Newman International Foundation, besides work for World Student Relief and World University Service. As a prison visitor for many years, he still takes a part in the Discharged Prisoners' Aid Society. He played an important part in the inauguration of the Industrial Museum of South Wales, which he serves as secretary, and has been president of the Royal Institution of South Wales. He remains very active in metallurgy, and at present is engaged in writing a further book.

### Mechanical Engineering in the Battersea College of Technology:

Prof. J. M. Zarek

DR. J. M. ZAREK, whose appointment to the chair of Mechanical Engineering and the headship of the Mechanical Engineering Department at Battersea College of Technology has recently been announced, was born in 1912 and received his engineering training at the Technical University of Warsaw. When Germany invaded Poland in 1939 he succeeded in making his way to Britain by a circuitous route and joined the Free Polish Army in Britain. Thereafter he studied at the University of St. Andrews, the Imperial College of Science and Technology and King's College, London. After three years as a

lecturer at the University of St. Andrews he joined the staff of King's College, London, in 1950, and, since then, has occupied posts as lecturer, senior lecturer (1956), and reader in engineering science (1961). Dr. Zarek's researches fall mainly into two fields. First, he was one of the first workers in Britain in the field of biomechanics, the application of the principles of engineering to problems in surgery and medicine. His work in this area of research has done much to establish and advance the science. Secondly, he has sustained an interest in the metering of pulsating flow and has served as the chairman of the International Standards Organization Working Group for Pulsating Flow Measurement.

### Voluntary Service Overseas

IN a written answer in the House of Commons on June 28, Mr. A. E. Oram, the Parliamentary Secretary to the Ministry of Overseas Development, stated that after consultations with the voluntary bodies and discussion in the Lookwood Committee, it had been agreed that the target for the graduate and qualified volunteer programme for 1966-67 should be 1,500. Voluntary Service Overseas intended to send out about 500 cadet volunteers (school-leavers and young volunteers from industry), and the Government would meet 75 per cent of the British costs of 400 of these cadets and of the 1,300 graduates. The programme of the graduate volunteers was only 100 more than this year's programme, which was proving difficult to complete. The voluntary bodies and the Government were agreed that quality should not be sacrificed for quantity and that in 1966 Britain should concentrate on strengthening the selection of projects. For this purpose the voluntary societies intended to arrange more frequent visits to the developing countries by members of their staff to discuss, at first hand, the selection of projects and to evaluate the work their volunteers were doing. Extra staff would be recruited where necessary and there would be fresh publicity to stimulate recruitment, including a film about volunteers produced by the Central Office of Information.

### European Organization for Nuclear Research

IN reply to a question in the House of Commons on July 1, the Secretary of State for Education and Science, Mr. A. Croxall, stated that the Government had agreed in principle to participate in the project for adding intersecting storage rings to the 28-GeV proton synchrotron of the European Organization for Nuclear Research at a cost of about £28 million, of which the United Kingdom's share would be rather less than £7 million over about 5-5 years. The formal decision might be taken by the participating States at a meeting of the Council in December. The intersecting storage rings would provide European high-energy physicists with a unique facility for maintaining a programme of advanced research.

### The United Steel Companies

STEEL is very much in the news at the present time and it is therefore not without pertinent interest to read the *Review of Progress 1964* recently published by the United Steel Companies, Ltd. (Pp. 52. Sheffield: The United Steel Companies, Ltd., 1965.) This report covers the period October 1, 1963, to September 30, 1964, and is specifically dedicated to all employees of the organization and their families; it thus makes available in easily understood language, accompanied by generous illustrations in black-and-white and colour, much inside information, technical and economic, which would otherwise perhaps be excluded from a more formal statement of affairs. 1964 was a record year for steel production in the United Kingdom, as indeed it was for the United Steel group. The total output of steel in Britain as a whole was 26.2 million ingot tons in 1964, nearly 2 million tons more than was produced in 1960, the best previous year. A

message from the chairman, Mr. A. J. Peech, in this report states: "The expectations of a prosperous outcome of the past year have been fulfilled and our works will continue to be fully occupied for, at any rate, the first part of 1965. It is, however, particularly difficult to forecast the effect on the longer-term outlook of the present balance of payments problem and the steps which are being taken to deal with it". The impressions to be gained from perusal of this report are those of a thriving and efficiently managed industry, an appreciation of the economic difficulties of the times, ability to live with and ultimately to surmount them, and a welcome basis of mutual understanding between executive and personnel from which alone future progress in this organization can be assured, whatever the ultimate political circumstances of the steel industry in Britain as a whole.

### Museums Journal

THE March issue of the *Museums Journal* (64, No. 4; 1965), in accordance with recent policy, is devoted to one subject. In this case, the work of the International Council of Museums is dealt with from several angles, in papers read at a one-day conference in London of the British members of the International Council. Present at the meeting was the president of the International Council, Sir Philip Hendy, who in his contribution to the conference did not minimize the difficulties facing those who want to make the International Council work well. The president of the British National Committee, Sir Frank Francis, spoke of the needs yet unmet by the International Council of Museums. Other speakers gave details of schemes of museum development that they had carried out in the United States, Poland, Russia, Tanganyika and Ghana, under the aegis of the International Council.

### Chemical-Biological Activities

A new journal, *Chemical-Biological Activities*, issued by the American Chemical Society, reports on the activity of organic compounds on biological systems exclusive of botanical. The digests indicate the host (if known), system (organ, etc.), function or characteristic of the system being modified, the condition created, the significant concomitant diseases or other conditions of the host or system, and the comparative drug activity and route of administration. Each bi-weekly issue contains three indexes, which will be combined and issued semi-annually. Further information can be obtained from Chemical Abstracts Service, the Ohio State University, Columbus, Ohio 43210.

### New Icelandic Islands: Surtsey and Surtling

THE new Icelandic island of Surtsey, born on November 15, 1963, about 32 km off the south coast of Iceland and 19 km south of the Vestmann Islands, has grown steadily since it first appeared above the waves, and by the spring of this year it had reached a height of 170 m and an area of 2.3 sq. km. Initially the volcano erupted ashes and steam and the island seemed likely to perish rapidly from marine erosion, as has been the fate of several new islands which have been recorded from time to time in the sea off south-west and north-east Iceland; but in April 1964, as soon as a sufficiently strong reef of tuffs was created to exclude sea-water from the vent, lavas began to be erupted, so ensuring a greater degree of permanence. In view of the widespread interest which the event aroused, the University of Reykjavik, the Museum of Natural History, and other Icelandic institutions set up a Surtsey Research Committee to co-ordinate and strengthen geophysical, geochemical, and biological studies of the island, and a first mimeographed report of the work of the Committee appeared in February 1965. Shortly after this another new volcano, now named Surtling, appeared about 0.5 km to the east of Surtsey.

Remarkable photographs of this eruption published in *The Times* on July 8, 1965, show that Surtling is already 250 m long and 20 m high. Prior to these outbursts the last volcanic island to be created off Iceland was that named Nyð south-west of Reykjanæs, on which the Danish flag was ceremoniously raised in 1788, the year of the disastrous fissure eruption of Laki; but Nyð was soon eroded to below sea-level. Surtsey is apparently made of sterner stuff and already there have been many aeroplane landings on its tuffaceous foreshore.

### The Wyeth Institute of Medical Research

THE Wyeth Institute of Medical Research at Taplow, near Maidenhead (Fig. 1), officially opened on June 22 by Lord Todd, is a 40,000 sq. ft., two-storeyed steel and concrete structure representing a £500,000 investment in research and development facilities for the future. It adjoins the Company's existing administrative headquarters, now two years old, while all production remains centred at the eight-year-old manufacturing plant at Havant, Hants. On the ground floor of the new research block are housed the two main Chemistry Departments, Medicinal Chemistry and Natural Products Chemistry. Here, too, are the physical chemistry, large-scale chemistry and radioisotope laboratories. Centrally placed on this floor are the laboratories, sterile suites and constant temperature rooms of the future Microbiological Department, at present based at Havant, but due to move into these premises in the near future.

Pharmacology, together with toxicology and the small-animal colony, occupy most of the first floor of the Institute. The animal colony, serviced from a central corridor running the length of the building, has been carefully designed to minimize contact between clean and soiled materials and to prevent the development of animal odours. Located in this unit also are an animal behaviour observation room and a fully-equipped operating theatre. The pharmacy laboratories of the Product Development Department are on the ground floor. The final sections of Wyeth research, chemical development, chemical manufacturing and accommodation for large animals, remain in Havant. The Taplow research building, with five separate air-treatment systems, hot and cold water supplies, high- and low-pressure steam, compressed air, distilled water, vacuum and gas services and an emergency electric generator in addition to the mains supply, contains in excess of £100,000 worth of equipment. Total research personnel strength, including administration and maintenance staff in Taplow, is 106.

### Ashmolean Museum, Oxford

THE report of the Ashmolean Museum for 1964 records that the rearrangement of the valuable Cypriote Collection is virtually complete and has enabled the pattern of cultures and settlement in the island to be illustrated with a clarity and interest not possible in its previously crowded condition (Report of the Visitors, 1964. Supplement No. 6 to the *University Gazette*, March 1965. Pp. 87. Oxford: The University, 1965. 2s. 6d.). New features include a display of material from the late Bronze Age sanctuary at Pigadhes-Myrtou, excavated by a joint expedition to Cyprus of the Universities of Oxford and Sydney in 1950-51. A major rearrangement and re-shelving of the Randolph basement has made it possible to move the Arundel Marbles in reserve, and also the Latin and Greek inscribed stones, to more accessible positions.

### Transvaal Museum, Pretoria

IN the report of the Transvaal Museum for the year ended March 31, 1964, it is recorded that the Namib Desert Research Station is now firmly established, and throughout the year workers in various fields of interest appertaining to conditions of extreme aridity have been carrying out research at the Station (Pp. 40. Pretoria: Transvaal Museum, 1965). Under the general title of *Scientific Papers of the Namib Desert Research Station*, some twenty papers have already been published. The buildings of the Station are well furnished, and the laboratory in particular is especially equipped with modern and valuable research instruments which, for the greater part, were given by the South African Council for Scientific and Industrial Research, and other research institutions.

### Science Museum, London

THE new Agricultural Implements and Machinery Gallery at the Science Museum, London, conveys in a simply understood way the technological complexity of modern farming methods. History has been used to emphasize the differences that have so greatly improved the agricultural workers' way of life. So far as possible, the exhibits themselves are so grouped that their message is more or less independent of the explanatory labels, but even these are set up in easily readable positions. The arable farming section is historically much as before in content. Modern arable farming is shown chiefly by a series of fifty new tractor and implement models set in new backgrounds and representing the four seasons of the year. The dairy farming section is entirely new.

Fig. 1. The new Wyeth Institute of Medical Research at Taplow

### New Sports Stadium at Rotorua, New Zealand

THE construction of a new indoor sports centre at Rotorua in New Zealand, built at a cost of £90,000 and recently opened, embodies some rather unusual features worthy of brief record. The total floor area is 41,000 sq. ft. and consists of three main sections: stadium, gymnasium and foyer. The stadium has a centre court playing area of 16,500 sq. ft. and provides tiered seating along two sides for 1,000 spectators. One of the important features of the design was the use of 120-ft. laminated timber arches to support the roof. The timber was local *Radiata* pine and an 'Aerolite' melamine-modified urea-formaldehyde glue was used for all laminating. Illustrated details of this construction are given in *CIBA Technical Notes* 264 (December, 1964. Pp. 7. Duxford: Ciba (A.R.L.), Ltd., 1964). Rotorua is situated in an area of thermal springs and geysers in North Island, and, because of the hazard in such an area of infiltration of hydrogen sulphide through the foundations, special treatment of the site was necessary and a 3-ft. raft of suitable filling material was made to provide a firm base. The laminated timber work alone consumed 50,000 super feet; the total quantity of timber used was 250,000 super feet, all *Radiata* pine except 50,000 ft. of heart matai used for the flooring. "To combat corrosion from sulphurous gases, galvanized nails were used in the floor, bronze rather than chromium-plated fittings installed and extensive use made of aluminium piping. Nearly two tons of galvanized nails were used and almost five miles of electrical wiring installed." In view of the insidious and far-reaching effects of hydrogen sulphide emanations in situations such as this 'sportsdrome' it is to be hoped that the filling material used (it is not named) to seal the site and ensure a firm base for the foundations proves adequate and permanent.

### University News:

#### Edinburgh

PROF. F. F. BONBALL, at present professor of pure mathematics in the University of Newcastle upon Tyne, has been appointed to the McLaurin chair of mathematics as from October 1.

#### Cambridge

THE following elections to fellowships at Churchill College have been made: *Title A*, Dr. J. D. Eshelby, on appointment as College lecturer in physics. *Title F (Overseas Fellowships)*, Prof. M. Gell-Mann, professor of theoretical physics at the California Institute of Technology (April-July 1966); Prof. J. A. Barnes, professor of anthropology at the Research School of Pacific Studies, Australian National University, Canberra (October 1965-February 1966).

#### London

PROF. G. W. A. DIJK, at present professor of microbiology at the Queen's University of Belfast, has been appointed to the Bland-Sutton chair of pathology tenable at Middlesex Hospital Medical School. The following readers have also been appointed: Dr. H. Stern (virology, tenable at St. George's Hospital Medical School); Dr. C. J. M. Stirling (organic chemistry, tenable at King's College); Dr. M. Spiro (physical chemistry, tenable at the Imperial College of Science and Technology). The following titles have been conferred: *Professor*, Dr. H. C. K. Henderson (geography, in respect of his post at Birkbeck College); Dr. D. Lacey (zoology, in respect of his post at St. Bartholomew's Hospital Medical School); *Reader*, Dr. A. G. J. MacFarlane (electrical engineering, in respect of his post at Queen Mary College); *Miss A. M. Coleman* (geography, in respect of her post at King's College); Dr. P. J. Lindop (radiobiology, in respect of her post at St. Bartholomew's Hospital Medical College).

### Proposed U.S. University Research Association, Inc.

THIRTY-FOUR universities in the United States have been invited to participate in Universities Research

Association, Inc., a new corporation formed as a result of a meeting of university presidents at the National Academy of Sciences on June 20, 1965. The corporation will offer its services to the Federal Government as manager of a proposed high-energy proton accelerator, should Congress approve its construction. Articles of incorporation, filed in the District of Columbia on June 21, list the following university presidents as temporary trustees: Detlev W. Bronk, Rockefeller University; Robert F. Goheen, Princeton University; Fred H. Harrington, University of Wisconsin; Grayson Kirk, Columbia University; Joseph R. Smiley, University of Colorado; Elvis J. Stahr, jun., Indiana University; H. Guyford Stever, Carnegie Institute of Technology; and John C. Warner, former president of Carnegie, who has headed the organizing committee.

Other institutions invited to participate in the corporation are: California Institute of Technology; University of California (Berkeley); University of California at Los Angeles; University of Chicago; Cornell University; Duke University; Harvard University; University of Illinois; University of Iowa (Iowa City); Johns Hopkins University; University of Maryland; Massachusetts Institute of Technology; University of Michigan; University of Minnesota; University of North Carolina; Northwestern University; University of Notre Dame; University of Pennsylvania; Purdue University; Rice University; University of Rochester; Stanford University; University of Texas; Tulane University; Washington University (St. Louis); University of Washington; and Yale University. The list is subject to later extension by the member institutions. The corporation will function under the authority of a council of presidents, in which each member institution will be represented by its chief executive. Its operations will be managed by a board of trustees, composed of six trustees-at-large to represent a broad section of public interest, and fifteen distinguished scientists and senior university administrators elected by the member institutions. The universities will form fifteen regional groups for the purpose of making these nominations.

### Announcements

PROF. S. PETERSEN, professor of meteorology in the University of Chicago from 1962 until 1963, has been awarded the International Meteorological Prize. The Prize is awarded for outstanding work in meteorology and international collaboration. It was established in 1955 by the World Meteorological Organization in honour of the former non-Governmental Organization which had initiated international collaboration in 1878 and which was replaced in 1951 by the World Meteorological Organization.

THE eighth European Congress on Molecular Spectroscopy will be held in Copenhagen during August 14-20. Further information can be obtained from the Eighth European Congress on Molecular Spectroscopy, Universitetsparken 5, Copenhagen Ø, Denmark.

A NATO advanced study institute on "The Biochemistry of Chloroplasts" will be held in the University College of Wales, Aberystwyth, during August 19-28. Further information can be obtained from Prof. T. W. Goodwin, Department of Biochemistry, Penglans, Aberystwyth, Cardiganshire.

THE 1966 congress of the European Organization for Research on Fluorine and Dental Caries Prevention will be held in Perugia during June 6-8, 1966. The main theme of the congress will be "Carbohydrates in Relation to Nutrition, Economic Standards and Dental Caries". Further information can be obtained from Prof. A. Seppilli, Istituto d'Igiene della Università, Casella Postale No. 150, Perugia.

## METHODS IN TAXONOMY

ON March 31 the Systematics Association held a one-day demonstration meeting at the British Museum (Natural History). This meeting attracted forty-five exhibits concerned with botanical, zoological and palaeontological taxonomy. The exhibitors were drawn from the British Museum (Natural History), University of Cambridge, the Imperial College of Science and Technology, the National Institute of Oceanography, the Nature Conservancy, New York State College of Agriculture, University of Oxford, Rothamsted Experimental Station, the Royal Botanic Gardens, Kew, the University of Leeds and the University of Manchester.

After a welcome had been extended by the Director of the Museum, the proceedings were opened by Prof. P. C. Sylvester-Bradley, president of the Association. Prof. Bradley heralded the meeting as a contribution to "the biological dialogue". He suggested that the controversy that had sprung up a few years ago between cell biologists (who stressed the unity of life) and systematists (who investigated the diversity of life) had now entered a constructive phase. In most universities and most schools of biology a debate was in progress which promised to initiate research in the fruitful field that lies in the region of overlap between cell biology and comparative biology. In investigating the diversity of life, taxonomy answers 'the what' of comparative biology, and systematics 'the how'. New methods in taxonomy supply an essential vitality to this biological dialogue.

The exhibits at the meeting were organized under five headings ("Collecting", "Preparation and Maintenance", "Examination and Extraction of Information", "Analysis and Synthesis of Information", and "Presentation and Dissemination of Results") and were laid out so that visitors were guided around the exhibition in this sequence. As the catalogue of exhibits suggested, this sequential classification—while representing an ideal picture of orderly progress through a programme of taxonomic research—cannot be assumed to represent the usual pattern of taxonomic work; nor are the five stages necessarily clearly recognizable.

Collecting is the process of sorting organisms from their environment, and, in so doing, concentrating them. The eight exhibits in the section on collecting illustrated the variety of ways in which this can be achieved. In most groups mechanical devices can increase the efficiency of collecting. These devices either exploit the behaviour of the organism or else overcome behaviour and the speed of movement. To the first group of aids belong equipment for the extraction of microarthropods from soil and the attraction of insects to light; to the second group belong the great variety of stationary and moving traps and nets.

In many instances neither the organisms nor the nets or traps are visible to the collector, and in these cases control of sampling is difficult to achieve; but it is interesting to note that only where collecting takes place in large water-masses, such as lakes or the sea, is it feasible to monitor the equipment and thus know exactly how it is behaving. Monitoring apparatus such as that used at sea for tracking the behaviour of nets are scarcely worth devising for collecting in other environments such as streams or dense herbage. A particular advantage of collecting devices lies in the fact that if the behaviour of the equipment is known accurately it becomes easy to sample quantitatively. For the most sophisticated taxonomy, giving the most highly predictive results, quantitative sampling is essential.

Sorting organisms from their environment does not itself produce useful collections, and without careful labelling and annotation even the finest collections are of limited use to the taxonomist. Great care and effort have gone into the preparation of labels which can carry, in standardized forms, information essential to the taxonomist. Even the lay-out and type-face of printed labels are important, having significance for the rapid sorting and selection of prepared specimens. Probably in no branch of biology has this been more clearly recognized than in botany. But, however clearly and neatly labels may be designed and printed, it is still necessary to ensure that the collector completes them intelligibly and permanently in the field. Collection labels are best accompanied by sets of hard-and-fast rules for their use.

While even quantitative sampling of the larger plants may require no elaborate apparatus, botanists face far greater difficulties in the preservation of their material in the field than do most zoologists and palaeontologists. Skinning or the rapid chemical fixation of animals do not compare with the lengthy and elaborate processes of drying, mounting and pressing of fragile plants—all processes which must be completed perfectly in the field if specimens are to be of value later. In contrast, the field preservation of fossils—while sometimes essential—is not always necessary. More often the palaeontologist is faced in the laboratory with the greatest difficulty in separating the fossils from their environment. Because of this the chemical development and mechanical separation of fossils are fields of highly developed technology.

The second section of the exhibition, concerned with the preparation and maintenance of organisms, was necessarily mostly concerned with methods which come within the domain of museum curation. Of particular interest were the exhibits which demonstrated the advantages to biology of the recent rapid advances in the fields of plastics and polymer resin technology, which allow impregnation and imbedding of such diverse structures as fossil and recent bones, plants and invertebrates. These newly available compounds and their properties have brought almost to the level of mass-production standards of mounting, dissecting, sectioning and display which were hitherto reserved for special exhibits, and which could be achieved only with the greatest labour. While some of these plastics and resins are useful both as preservative and preparatory media, other new compounds have been developed for the bulk preservation and storage of organisms. Perhaps the most important of these is phenoxetol, which, with its good properties as a preservative, its low price, absence of smell, and avoidance of fire risks, promises to be a useful substitute for alcohol and formalin in large collections. Another significant innovation, increasingly used in museums, is the practice of freeze-drying whole specimens, when colour, shape, texture and posture of even quite large vertebrates can be most amazingly retained.

A specimen preserved for several decades by any technique is of little use if the labels that accompany it have deteriorated. In recent years much research has been done to determine the qualities of paper and ink which will remain intact and unfaded for many years in both herbarium and spirit store, despite wide fluctuations in temperature, humidity, and other features of the environment. Furthermore, not only must labels not deteriorate, but in design and layout they must be as clear in the store as they are to the collector in the field.

Surprisingly, perhaps, few exhibits in this section dealt in detail with the administration of large collections. All the more interesting therefore were the exhibits of the curation of extensive insect and mammal collections, which demonstrated the importance to taxonomic research of type specimens, named series, and the most effective physical arrangements of animals of widely varying shapes and sizes. The proper curation of large collections requires speedy and accurate storage and retrieval, not only of objects but also of information about the objects. This presents a problem that is further complicated by the difficulty of deciding how much information the objects themselves display and how much should be documented. As exhibits in the sections of the demonstration on analysis and synthesis and presentation and dissemination revealed, this complication is becoming increasingly troublesome. Small collections made for special research purposes appear to be readily suitable for documentation with punched cards, special maps and other recent innovations.

The exhibits displayed in the section dealing with examination and extraction of information were all concerned with methods of obtaining information not immediately detectable without the help of instrumentation, and this section, perhaps more than any other in the demonstration, showed how very many developments in the physical sciences are rapidly turned to their advantage by taxonomists. Two exhibits of striking electron-micrographs complemented nicely a demonstration of the range of light microscope techniques. X-ray illustrations of skeletal structures, moulds of leaf surfaces, and electronic recordings of insect sounds were the themes of other exhibits showing exploitation of techniques which might be thought to belong solely within the fields of the physical sciences.

Demonstrations of the uses to taxonomists of paper chromatography, electrophoretic separation of proteins, and a variety of serological techniques indicated the increasing significance to taxonomy—especially of  $\gamma$ -taxonomy—of advances in biochemistry.

Many techniques and instruments can provide the taxonomist with assessable information, and a point which the exhibits in this section underlined is that no one technique, whether simple or the ultimate in sophistication, can be held to be the most useful. It was perhaps unfortunate that there was no exhibit which demonstrated the usefulness in taxonomy of the unaided human senses and such simple instruments as callipers.

Just as the significance to taxonomy of the human senses is not easy to display, so the vital importance of human mental processes of induction and deduction did not lend themselves readily to demonstration in the section on analysis and synthesis. The ever-increasing use of mathematical and geometrical methods of analysis and synthesis in taxonomy was demonstrated by the use of geometrical transformations of structure and a wide array of methods of multivariate analysis. The development of these last techniques, which is closely linked with advances in computer technology, allows taxonomists to take on research problems which, in the past, would have required many years for completion—if indeed they could

have been contemplated—but which can nowadays be completed in a few weeks or months. Numerical treatment of taxonomic data is still a subject of much controversy; but there can be no doubt that its use encourages taxonomists to regard the organisms with which they deal as parts of populations. This is essential for progress in some areas of taxonomy; but what is urgently needed, if numerical taxonomy is to become an accepted tool of routine identification and classification, is proof that the labour of collecting the vast quantities of data required for the statistics is rewarded by greatly increased usefulness of the results.

Numerical methods of analysis and synthesis may allow taxonomists to handle rapidly large amounts of data; but, as the section concerned with presentation and dissemination of results showed all too clearly, biological data are not the only items which are accumulating faster than they can be handled by traditional methods. Collections of organisms are growing rapidly all the time, and will continue to grow at a high rate for many years to come. Every specimen is a source of useful information, and so, ideally, every specimen should be easily retrieved from the collection, while the information which accompanies it should be readily available. Unfortunately, because of the continued growth of collections, and because the theories and practice of information storage and retrieval are still in an early stage of development, probably all institutions which maintain large collections are faced with apparently insuperable problems of management. While collections the items of which can be counted in hundreds can be adequately controlled and used by means of written guides and indices, these time-honoured methods cannot be efficient where collections must be numbered in tens or hundreds of thousands. Considerable thought is now going into the design of machinery and procedures which can deal efficiently and rapidly with the documentation and control of large collections. If these efforts are successful the exchange of information and material between taxonomists could be greatly improved.

Not only are collections of organisms expanding at a tremendous rate but the volume of published work which each taxonomist must review grows every year. Collection management and the control of published results have many problems in common, and many of the same principles are employed to devise information storage and retrieval aids in both fields. However, some problems of bibliography control can be solved more easily than can their counterparts in collection management. Uniform high standards of illustration, typography and layout can be demanded, as can condensation of text, but organisms to be stored will always be highly heterogeneous in the amount of information which they reveal on casual inspection and in their storage requirements. It was clear from several exhibits in this section that much taxonomic publication could be standardized to allow efficient storage and easy perusal. Ideas differ as to the best ways of achieving these aims, and it is to be hoped that some measure of agreement will be reached soon. Otherwise the taxonomist will find himself forced to read yet more journals with different and conflicting methods of presentation.

WILLIAM G. FRY

## TELEVISION AND RADIO IN BRITAIN

IN opening a debate on broadcasting in the House of Commons on May 13, Sir Peter Rawlinson pressed for information as to the Government's plans for television and advocated that the new fourth channel should be devoted to commercial television. As regards sound broadcasting, he thought that this was the appropriate time to encourage local broadcasting and the right

solution was to be found in low-range local broadcasting stations. In replying for the Government, the Postmaster-General, Mr. Wedgwood Benn, said that it was essential before taking a decision on the allocation of the fourth channel that we should be clear as to what purposes the fourth channel should be required to meet. Educational broadcasting was very closely tied to the question of the

fourth channel and this was being urgently considered, as well as the alternative possibilities, including the utilization of unused hours; decision would only be reached after most careful consideration of the alternatives.

On colour television, he said that the failure of the Vienna Conference to reach agreement on an acceptable uniform colour system in Europe had set back our hopes of European standardization. For Great Britain, the choice, if one had to be made, lay between American and European systems and would be a particularly difficult one, which would be even harder if there were two different systems on the Continent of Europe and not just one. We would also have to consider the question of payment for colour television, and it might not be right to ask the main body of licence holders to pay for a colour service which they may never wish or be able to afford to receive themselves.

Pirate ships had no part whatever in the future development of broadcasting in Britain or in Europe. They were interfering with reception in other countries, and the development of a really serious pattern of local sound stations in Britain depended on the use of very high frequency which made a great number of channels available.

Mr. Benn restated the traditional doctrine which had been accepted by all governments and was designed as a safeguard against political interference. There was a great danger in going beyond this limit with regard to ministerial interference. Mr. Benn insisted that the increase of the licence fee was fully justified and would only hold the present position and keep the British Broadcasting Corporation within its present borrowing limits. We had reached a point where the Corporation could no longer rely in anything like the previous extent on increased revenue arising from new licence holders. The Government was satisfied that all reasonable economy was

exercised within the Corporation, and the review in which the Corporation was co-operating was instituted in view of the changed position for increased revenue.

The problem of evasion was also being examined. In reaching its decisions, Mr. Benn said the Government would be guided by its profound belief in the growing importance of radio and television to the community and to the world, by its desire to see television and radio expand as rapidly as national resources permitted, to meet important national needs and to develop still further their potential for education, information and entertainment. It also recognized that technological changes had opened up new possibilities which had hitherto been entirely excluded. It was determined to uphold and entrench the principle of public service in all further development in television and radio, and it also wished to allow the greatest possible freedom and scope for creative talents to express themselves through radio and television. It was prepared to consider fully the various methods by which broadcasting could be financed, including a combination of broadcasting licences, grants-in-aid, local government grants and advertising revenue under proper supervision.

Mr. W. Shephard, who followed, agreed that a decision on the fourth channel should not be rushed, but he did not wish to see existing contractors given any more scope, or contractors obtained who had made fortunes elsewhere. He and subsequent speakers were somewhat critical of standards maintained by the British Broadcasting Corporation, and in the debate there was strong support for the development of local broadcasting. Mr. H. Bowden, replying for the Government, added little to what Mr. Benn had said, but reiterated the need for increased educational facilities and the dependence of a decision on the fourth channel on a careful review of the whole situation.

## EXPERIMENTAL EVIDENCE OF A TWINKLING LAYER IN THE EARTH'S ATMOSPHERE

By CRAIG C. HUDSON

Sandia Corporation, Sandia Base, Albuquerque, New Mexico

THE scintillation of stars is that part of astronomical seeing which deals with intensity fluctuations of the image, more commonly called twinkling. A large part of twinkling occurs at frequencies too high to be observable to the human eye, that is, greater than 15 c/s. For many years the cause has been thought to reside in the atmosphere, in the form of fluctuations in the index of refraction caused by air turbulence.

Other optical effects, such as blurring and dancing of the image, often accompany twinkling, but can be distinguished from it both by the method of observation and by layer of origin in the atmosphere.

Reviews of the various experiments and theories of astronomical seeing (especially twinkling) are included in Tatarski's well-known monograph<sup>1</sup>, in the report by Keller *et al.*<sup>2</sup>, and in the report by Wimbush<sup>3</sup>. The present discussion will be limited to twinkling.

The observational properties of star twinkling have been reported by many<sup>4-7</sup>. It is least in the zenith direction and has the broadest frequency spectrum there. For low angles of observation, the amplitude increases but the high frequency end of the spectrum fades away. The spectrum near zenith is approximately flat below 100 c/s but falls off rapidly at higher frequencies. Twinkling is enhanced by the use of a small aperture, and tends to a minimum for apertures greater than 20 in. diameter. For small apertures, the modulation (fluctuation relative to mean light level) can exceed 100 per cent even at the

zenith, while for large apertures 10-20 per cent is more typical. Twinkling also depends on the source size; the larger planets, for example, showing very little effect. Finally, twinkling depends on meteorological conditions; in particular, there is correlation between the intensity of the effect and the speed of winds above 20,000 ft.

Contemporary theories of twinkling, according to Keller<sup>2</sup>, can be classified into three groups: (a) those governed by the refraction of light by turbulent elements of large size not too far from the observer (also contributing to blurring and dancing); (b) those governed by the diffraction of light with the zeroth order predominating (thin layer); and (c) those governed by the diffraction of light with the higher orders predominating (thick layer). Using a theory of type (a), Chandrasekhar<sup>8</sup> deduced that twinkling could be explained on the basis of a hypothetical layer 100 m thick, of homogeneous, isotropic turbulence at 4 km altitude. Keller suggests a thinner layer at a higher altitude. Wimbush argues against a discrete layer, citing evidence of several other workers in favour of a continuous distribution of turbulence.

Keller<sup>2</sup>, using Protheroe's autocorrelation data<sup>9</sup>, made a parameter study on the basis of the theory of scintillation<sup>10,11</sup> which is of interest in what follows. The scale of turbulence is  $L_m$ ;  $\Delta z$  is the layer thickness; and  $\delta^2 n$  is the mean square fluctuation of the index of refraction. By assuming no pressure fluctuations,  $\delta^2 n$  may be transformed into the mean square temperature fluctuation  $\delta^2 T$ . Estim-

ates of  $L_m$  range over factors of two while  $\Delta z$  and  $\delta T$  are uncertain by orders of magnitude. The primary variables in the theory of scintillation, therefore, are the thickness of the turbulent layer and the intensity of its turbulence. Keller's parameter study is partially reproduced in Table 1. In each case, the experimental data are satisfied by a different set of parameters (assuming isotropic turbulence with a Gaussian distribution of element sizes).

Table 1					
Parameters	March 1, 1964			March 16, 1964	
Altitude $z$ (km)	6.1	9.2	15.3	9.2	15.3
$L_m$ (cm)	6.7	5.9	6.3	6.7	6.7
Thickness $\Delta z$ (km), ( $\sigma^2 T$ ) <sup>1/2</sup> = 0.1° C	0.361	0.043	0.14	0.021	0.037
Thickness $\Delta z$ (km), ( $\sigma^2 T$ ) <sup>1/2</sup> = 0.01° C	6.1	4.3	14	2.1	3.7

Keller rejected the second set of thicknesses on the grounds that adiabatic mixing through such a thick layer would produce r.m.s. temperature fluctuations greatly in excess of 0.01° C.

Light beacons suspended from balloons which drifted with the wind have been used to study scintillation by Gardiner *et al.*<sup>12</sup> and Mikecell<sup>6</sup>. The twinkling due to the lights was compared with that due to nearby stars. The amplitude twinkling in the range 1–10 c/s of the beacons was 50–75 per cent less than that of stars, and in the range 147–153 c/s was more than a factor of two less than that of the stars.

They also studied scintillation as a function of the correlation of light pulses due to double stars. In the frequency range 1–10 c/s, the twinkling appeared to arise from altitudes of 100,000 ft. or higher. For higher frequencies, about 150 c/s, the twinkling appeared to be caused near 30,000 ft. To account for the high-altitude low-frequency variations, they suggest that there exist large density variations in the atmosphere at these levels, essentially at rest relative to the Earth, which are swept through the line of sight to the star by the Earth's rotation.

Some new experiments are now being made which may shed additional light on the structure of the atmosphere and the causes of stellar twinkling. The first of these is reported here.

The idea of the experiment was to allow a point source light beacon to fall through the twinkling region, observing it continuously with a telescope fitted with a recording photometer. The beacon was carried to 65,000 ft. as the pay-load of a 6-in *Apache* rocket motor. To restrain the free fall somewhat, to keep the light on the bottom of the body, and to allow the beacon to sink more nearly vertically, a small parachute was deployed which caused the sink rate to be about 300 ft./sec at 30,000 ft. altitude. A 16-in. tracking telescope fitted with an RCA '7265' photomultiplier cooled with carbon dioxide was used to observe scintillations. No filters were used, so white light was observed.

The experiments were performed at the U.S. Atomic Energy Commission's rocket range at Tonopah, Nevada, at an elevation of 5,300 ft. A strong cold wind was blowing on the night of December 11, 1963, the air was dry, and visibility was nearly unlimited although a small amount of fine powder snow was being blown around at low levels. On March 10, 1964, the air was again clear, cold and dry, but the wind was calm, a front having passed the night before. Meteorological data were taken by radiosonde as often as practicable (every 2–3 h). Position of the beacon was obtained both by radar and by an optical triangulation system. Altitude accuracy is about  $\pm 200$  ft. Altitude accuracy of the radiosonde is believed to be no worse than  $\pm 300$  ft.

The scintillations were recorded on magnetic tape after being telemetered from the remote telescope site. The telemetry used a 70-kc/s channel on a 220-mc carrier. The frequency response of the system was limited by the telemetry to the range DC to 10 kc. The tapes were then played back to give (a) a measure of the twinkling

amplitude as a function of time and (b) a measure of the frequency spectrum.

In addition to observations of the falling beacon, scintillation measurements were also made on ground lights at various distances, on a number of stars and planets, and on the satellite *Echo I*. The purpose of these measurements was mainly to check and calibrate an untried system, but also to make available a more complete set of twinkle measurements.

The data from the beacons are shown in Fig. 1 in the form of percentage modulation of the mean light intensity. The values are weighted in favour of frequencies between 10 and 100 c/s. A sample of the frequency spectrum of the

Fig. 1. Evidence of twinkling layer. Scatter in the data is partially due to hand reduction

Fig. 2. Frequency spectrum of twinkling signals. System capability and data actually recorded were good to 10,000 c/s, but reduction technique was not reliable above 1,000 c/s

twinkling of the beacon above the layer and below the layer is shown in Fig. 2.

The meteorological data are shown in Fig. 3. Data points are about 400 ft. apart. A tentative assignment of the tropopause has been made. The horizontal bars indicate approximately the twinkling layers.

Referring to Table 1, the set of parameters which best corresponds to the present measurements comprises those of the altitude 9.2 km which imply r.m.s. temperature fluctuations of the order of  $0.01^\circ\text{C}$ , appreciably smaller than the estimates typically seen. Of course, if the observed layer actually consists of several thin layers, the temperature fluctuations need not be so small.

From Fig. 3 one gets the impression that the twinkling layer is not associated either with the wind speed structure or with the tropopause; but since it seems typically to occur in that neighbourhood, a re-check of the wind vectors was made to see if strong shears or wind gradients could be found in the layer; but the shears in those regions were no greater than in nearby regions where a change in twinkling was not observed. The U.S. Weather

Bureau maps for the days in question showed no jet stream in the near vicinity.

The peak intensity of scintillation on December 11 was probably not more than 30 per cent modulation, and on March 10 scarcely more than 15 per cent modulation. Unfortunately, no measurements were made on stars at the zenith, but for Capella ( $30^\circ$  from the zenith on December 11) and Pollux ( $10^\circ$  on March 10) the approximate intensity can be found by making a sec<sup>2</sup> $\theta$  correction. The values obtained in this way were 33 per cent (December 11) and 18 per cent (March 10). These data indicate that only a small fraction of the total scintillation above 10 c/s occurs above the measured twinkle zone.

By the experiments already performed, the existence of a twinkle layer, long suspected, has been confirmed. The height of the layer corresponds roughly to the tropopause, although no unique relationship seems to exist between the layer and either the tropopause or wind structures. In terms of Keller's theory of twinkling, the layer thickness corresponds to temperature fluctuations of the order of  $0.01^\circ\text{C}$ , somewhat smaller than has been conjectured. In the higher frequency portion of the spectrum (above 10 c/s), it seems that about 80 per cent of the total twinkling occurs in this layer, about 10 per cent below it, and 10 per cent above.

A second experiment now in progress will attempt to measure temperature fluctuations directly and to relate them to the observed twinkle layer. The mean square temperature fluctuation  $\delta^2 T$  will be determined at the frequency that seems to be most prominent, and this frequency (corrected for the rocket's motion) will also establish the scale of turbulence. As a precaution, microphones will also be used to determine the level of pressure fluctuations, and the instruments are so mounted that correlations between pressure and temperature fluctuations can be made.

This work was supported by the United States Atomic Energy Commission.

## VEMA SEAMOUNT

By Prof. E. S. W. SIMPSON and A. E. F. HEYDORN

Department of Oceanography, University of Cape Town and Division of Sea Fisheries, Cape Town

THE Vema Seamount is situated in latitude  $31^\circ 38' \text{S}$ , longitude  $8^\circ 20' \text{E}$ , near the centre of the Cape Basin, South Atlantic Ocean, approximately midway between the Walvis Ridge and the South African mainland. It was discovered in 1959 during cruise 16 of the Lamont Geological Observatory research vessel *Vema*. The seamount base is approximately 35 miles in diameter at ocean floor-level (2,500 fathoms) and the overall slope inclination is 1 in 4, or  $15^\circ$ , terminated upwards by a plateau of some 5 miles diameter and 40 fathoms depth from which the highest peak rises to within 14 fathoms of sea-level.

With the co-operation and generous assistance of the Marine Diamond Corporation a fairly detailed investigation of the seamount summit zone was carried out in November 1964, using scuba divers and the special air-lift dredging equipment in the diamond prospecting vessel *Emerson K* which enabled bottom samples up to 4 in. in diameter to be recovered in great quantity to depths of 45 fathoms.

Using radar fixes from a centrally positioned reflector buoy, bathymetric survey traverses totalling approximately 170 miles were run along radial lines at  $30^\circ$  intervals and along a number of tangential lines to fill in detail.

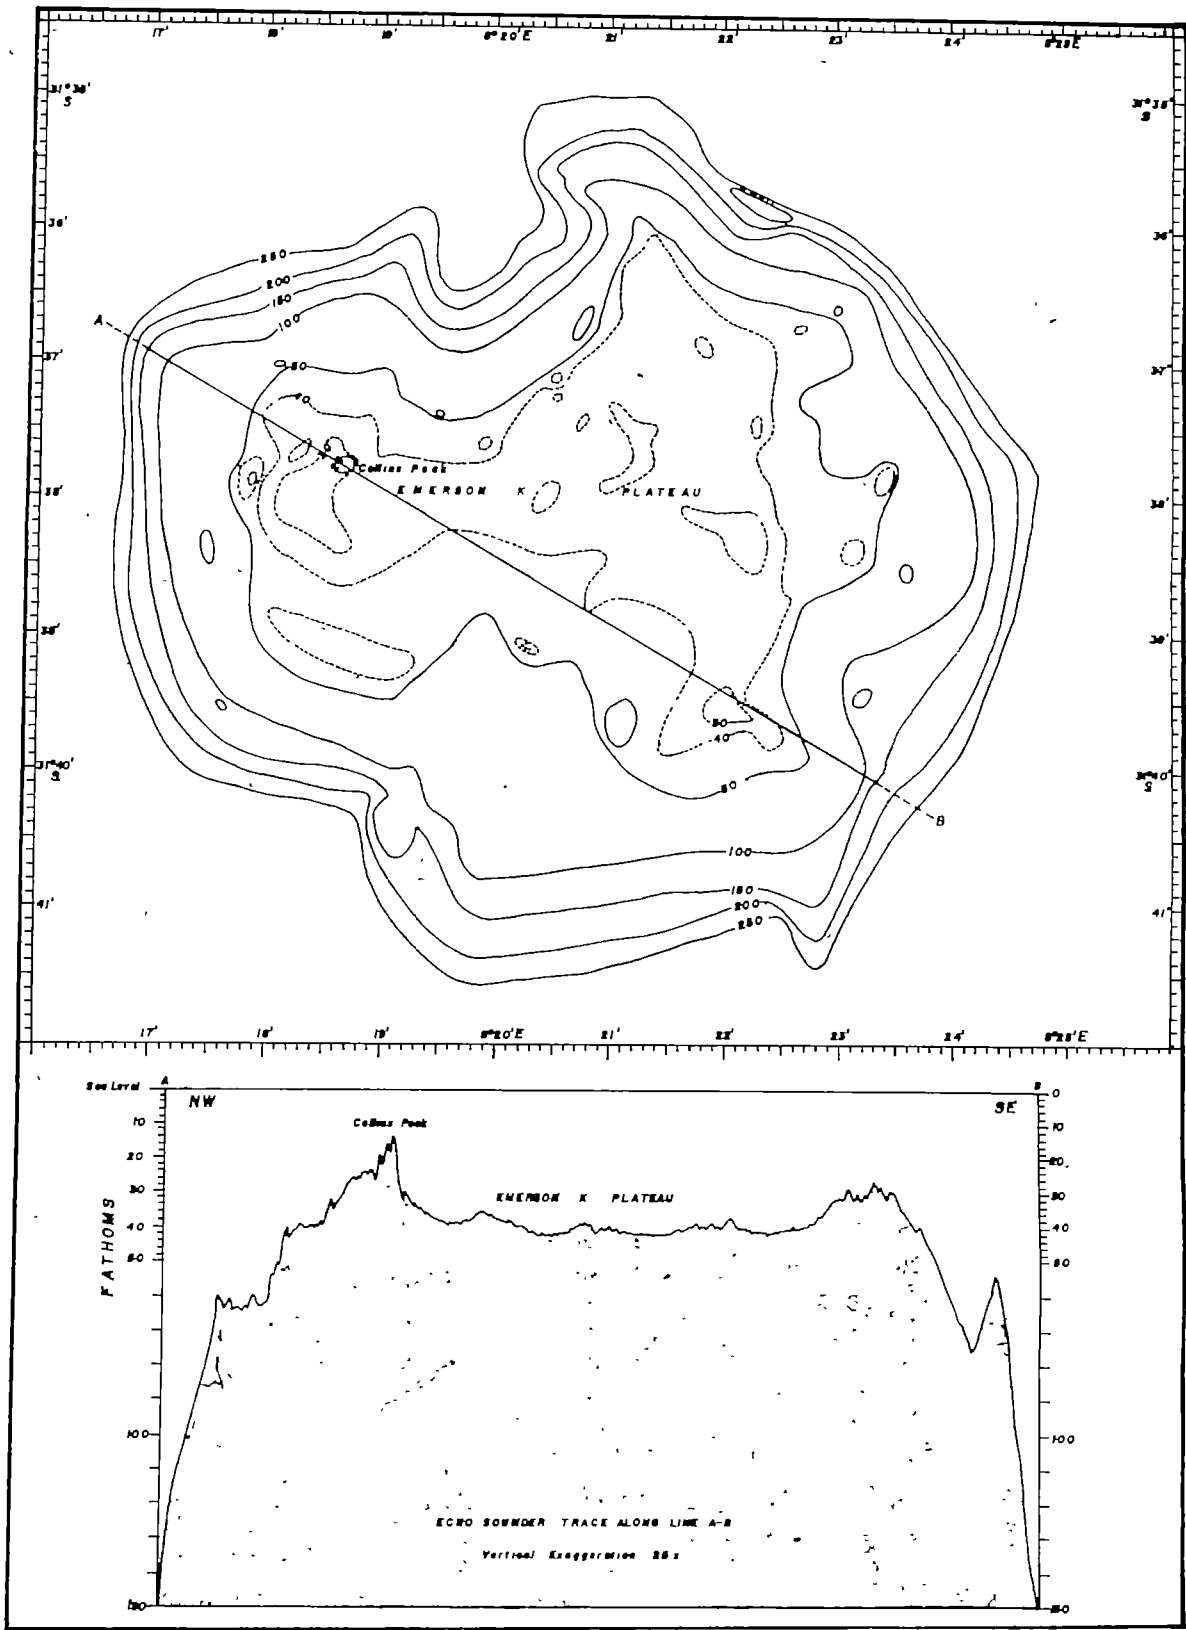

Fig. 1. Provisional bathymetric chart and profile of the Vema Seamount summit zone. Depths in fathoms

The plotted data were used to compile the accompanying provisional bathymetric chart and profile of the summit zone (Fig. 1). At the 250-fathom isobath the seamount is roughly circular in plan with a diameter of some 7 miles. Slope gradients are generally low above the 70-fathom isobath, but below this level the flanks are steep ( $\pm 15^\circ$ ) and broken in places by occasional subsidiary peaks.

The seamount is capped by a well-defined shelf (Emerson K Plateau) of mean depth 40 fathoms from which rise several eminences, particularly near the margins, of which the highest is the steep and rugged Collins Peak. The Emerson K Plateau occupies an area of approximately 5 square miles. The consistent depth of the Plateau and the frequent recovery from it of rounded boulders and pebbles suggest strongly that it is a wave-cut platform which probably corresponds to a eustatically lowered sea-level during the Pleistocene. Another persistent bevel, probably also wave-cut, was noted on most traverses at a mean depth of 60 fathoms (see Fig. 1, profile).

Approximately a ton of bottom samples was recovered by the air-lift dredge at six different localities and several specimens of bedrock *in situ* were collected by scuba divers.

The rugged submarine outcrops on Collins Peak are composed of a dense green phonolite which comprises small nepheline phenocrysts set in an aphanitic ground-mass of nepheline, aegirine-augite, a little alkali feldspar and iron ore, with much clear isotropic glass. A  $^{40}\text{K}/^{40}\text{Ar}$  determination made on a sample of the phonolite by Dr. Ian McDougall in the Department of Geophysics, Australian National University, has yielded an age of  $11.0 \pm 0.3$  million years. Owing to the possibility of loss of argon, this value must be regarded as a minimum age.

All rock samples taken on the Emerson K Plateau consisted of medium to dark brown tuffaceous agglomerate or volcanic ash of basaltic composition, many of them rounded. A few rounded boulders of black amygdaloidal olivine basalt were recovered only at one station, south of Collins Peak.

Geomagnetic measurements were made over approximately 60 traverse miles with an Elsec proton precession magnetometer by Mr. K. Biehevel of the Anglo-American Corporation. Preliminary results indicate a regional magnetic field intensity of  $29,700 \pm 100 \gamma$  at some distance from the seamount. An area of low magnetic values ( $29,000 \gamma$ ) is centred on Collins Peak, with values of 29,400 and 29,850  $\gamma$ , respectively, to the north and over the south-eastern edge of the Emerson K Plateau. Several local anomalies on the plateau show 'lows' to the north accompanied by 'highs' to the south, which suggests that the causative bodies are reversely magnetized.

As an isolated peak in the ocean, reaching within the zone of sunlight penetration but separated from the neighbouring mainland and islands by barriers of depth as well as distance, the Vema Seamount harbours an exceptionally interesting and abundant biological community hitherto unspoiled by commercial exploitation.

At all dredging stations on the Emerson K Plateau great quantities of rounded calcareous accretions up to 3 in. diameter were recovered. Many of these have a botryoidal outer surface with a thin pink layer coating, beneath which are concentric calcareous layers which in many examples surround a small rounded pebble of volcanic ash. After a cursory examination, Prof. J. H. Day reports that the encrusting material consists mainly of coralline or lithothamnian algae but includes also non-calcareous algae, Foraminifera of at least two species, sponges, serpulid and other worm tubes, and Bryozoa.

Steep-sided rock gullies on the bottom contain accumulations of finely comminuted calcareous debris which include arenaceous and calcareous Foraminifera, several species of gastropod, pelecypod and bryozoan fragments, some echinoderms and worms.

Collections of sessile benthic fauna and flora were made from depths ranging from 14 to 40 fathoms by scuba divers and the air-lift dredge. The rocky bottom is covered by a prolific and varied growth of sponges, hydroids, ascidians, a large species of holothurian, and seaweeds with abundant kelp (*Ecklonia* sp.). The fresh remains of three small oysters were recovered at one locality. It is of interest to note that the composition of the benthic fauna is not typically South African and appears rather to show zoogeographic affinities with Tristan da Cunha.

Rock lobsters (*Jaanus tristani*) were observed in great numbers by scuba divers and 111 were recovered for examination. The sample comprised 88 males and 23 females, with very few juveniles. The most abundant size (cephalothoracic length) of the males was 5.5-5.9 in. and that of the females 3.9-4.3 in. Of particular interest is the similarity to the rock lobsters of Tristan da Cunha. Intensive commercial exploitation of this community is now in progress, and examination of a large sample of the initial catches has confirmed the size frequency distributions as observed during the expedition. Further catches will be examined at regular intervals, as the intensive exploitation of the restricted and geographically isolated population on this seamount should afford a unique opportunity of observing the effect of fishing on a virgin resource.

An abundance of fish was observed by scuba divers and confirmed by hand-line fishing with the following results:

Species	No. caught	Size range (in.)
<i>Seriola lalandi</i>	58	27-48
<i>Acanthaluteres monodactylus</i>	42	15-25
<i>Poliprion americanus</i>	3	30-40
<i>Decapterus longimanus</i>	4	10-12
Undetermined species	3	$\pm 10$

The similarity to fish from Tristan da Cunha is again striking. No sharks or other elasmobranchs were observed (sea surface temperatures varied between  $18.3^\circ \text{C}$  and  $18.8^\circ \text{C}$ ) although many have appeared on the scene since the onset of commercial fishing operations.

Over the seamount random currents of variable direction, strength and duration were very evident during the course of the survey, which lasted four days. As the Emerson K was not equipped with hydrographic winches or davits, observations with regard to hydrology and planktology were necessarily restricted and will have to be augmented by further observations during a proposed visit by an oceanographic research vessel to the seamount in the near future. According to Mr. M. J. Orren and Dr. A. de Decker of the Division of Sea Fisheries, who analysed the hydrological and planktological samples respectively, the temperature and salinity values on and around the seamount are characteristic of Central South Atlantic Ocean waters and, further, suggest local sub-surface upwelling of cold, nutrient-rich Antarctic Intermediate water, which has a strong northerly component of flow in this region. This view is strengthened by the presence, in a single vertical plankton haul which was taken above the plateau, of the copepods *Calanoides carinatus* and *Calanus tonsus* (typical of Sub-Antarctic water) among a great majority of South Atlantic warm-water forms. The sample as a whole revealed a rich plankton community with a high volume for an oceanic station. More than 40 adult euphausiids (*Euphausia recurva* and *Thysanoessa gregaria*) indicate a high organic production.

All the data and material collected from the seamount are being processed by specialists who will in due course publish the results in greater detail. Only the uppermost one-tenth of the seamount was examined during the 1964 visit and much material remains to be collected in the course of future cruises.

# STRONTIUM ISOTOPE COMPOSITION AND POTASSIUM-RUBIDIUM RATIOS IN SOME ROCKS FROM RÉUNION AND RODRIGUEZ, INDIAN OCEAN

By DR. IAN McDOUGALL and DR. W. COMPSTON

Department of Geophysics and Geochemistry, Australian National University, Canberra

THE isotopic composition of strontium and the potassium/rubidium (K/Rb) ratio are useful geochemical parameters in the understanding of the genesis of history of rocks<sup>1-4</sup>. Because most volcanic rocks in oceanic regions must be derived from the upper mantle with the minimum possibility of contamination from crustal materials, the examination of such rocks is of value in placing restrictions on the composition and chemical evolution of the upper mantle.

In this article we present results obtained on a series of rocks covering a wide range of composition from the volcanic island of Réunion, Indian Ocean. Two samples also were analysed from Rodriguez, an island which lies about 800 km east of Réunion. The aims of the work recorded here were first, to contribute to the question of the geographic homogeneity of the isotopic composition of strontium and the K/Rb ratio in rocks derived from the upper mantle, to which end much current work has been directed<sup>1-4,7-11</sup>. Secondly, we wished to use these two parameters to examine the relationship between the various rock types, and to see whether a correlation exists between the values found and the bulk chemical composition of the rocks.

Réunion lies near the south-west limit of the Mauritius-Seychelles Ridge, some 700 km east of Madagascar. The island is elliptical in outline with major diameter of 75 km and minor diameter of 55 km; it is built of two volcanoes. Piton des Neiges, an extinct volcano, occupies the north-western two-thirds of Réunion, and rises to an altitude of 3,069 m. Much of the original form of the volcano is preserved, although the central parts are deeply eroded into spectacular 'cirques', in which volcanic breccias are of common occurrence. Rivals<sup>12</sup> and Upton and Wadsworth<sup>13</sup> showed that Piton des Neiges is built of basaltic lavas covered by an extensive veneer of later lavas consisting mainly of alkali andesites. Piton de la Fournaise, which forms the south-eastern part of Réunion, is an active volcano rising to an altitude of 2,631 m. It is constructed entirely of basaltic lavas. Most of the rocks that have been analysed from Piton de la Fournaise are normatively slightly undersaturated with respect to silica, but rarely show nepheline in the norm<sup>14</sup>. Tilley<sup>15</sup> noted that these basalts are tholeiitic, and the few analyses available from Piton des Neiges suggest that this volcano also may be built of tholeiites. Petrographic examination of a number of samples lends support to this conclusion. The volcanoes of Réunion appear to be very similar as regards composition and evolution to those of the Hawaiian Islands, although the potassium content in Réunion tholeiites is considerably higher than in tholeiites from Hawaii. Most volcanoes exposed in oceanic basins appear to be composed of alkali lavas; however, based on the evidence from Hawaiian volcanoes, Tilley<sup>15</sup> suggested that the primary magma in oceanic regions may be tholeiitic basalt, from which the alkali lavas are derived by fractionation. This conclusion is strongly supported by recent investigations of samples dredged from the ocean floors<sup>16</sup>. In 1964 samples were collected from Réunion by the senior author for K-Ar dating, palaeomagnetic and geochemical, including isotopic, investigations. Preliminary dating on these rocks shows that the older basalts of Piton des Neiges are about 1 m.y. old, with some later basalt flows as young as 0.5 m.y., and that the veneer of alkali andesites is younger than 0.5 m.y. Piton de la Fournaise has been active over at least 0.19 m.y.

The rocks chosen for analysis in the work recorded here cover a wide range of composition. From Piton des Neiges three basalts, three alkali andesites and a syenite were analysed. From petrographic examination the basalts appear to be tholeiites, and the alkali andesites (1257, 1264) resemble hawaiites, whereas 1260 is similar to mugearite. The syenite sample (1266) is from an irregular transgressive sheet more than 100 m thick intrusive into agglomeratic material in Cirque de Cilaos. This rock, described and analysed by Lacroix<sup>14</sup>, is a peralkaline syenite consisting mainly of perthitic feldspar with aegirine and soda amphibole. Of the two samples analysed from Piton de la Fournaise 1263 is an olivine basalt (tholeiitic?) from a series of thick lava flows, possibly filling an old caldera in the older parts of the volcano. Sample 1267 is a tholeiitic picrite basalt (oceanite) from the 1961 lava flow.

Rodriguez is an extinct volcano, the exposed lavas of which are alkali basalts<sup>17</sup>. Two basalts, dated at 1.3-1.5 m.y. old, were analysed in this investigation.

For the determination of <sup>87</sup>Sr/<sup>86</sup>Sr, strontium from representative aliquots of 50-g whole rock samples was concentrated by cation exchange, and isotopically analysed as the chlorides on a 12-in. radius of curvature 60° sector mass spectrometer using a triple filament ion source and a single plate collector. Isotope ratios were measured by switching the accelerating voltage; details of this technique will be given elsewhere<sup>18</sup>. Measurements were made with the collected <sup>86</sup>Sr beam equal to 2.5 × 10<sup>-11</sup> amperes or greater and the digitized output system described earlier<sup>18</sup> was used to obtain sensitivity and linearity at the 0.05 per cent level. Corrections to the measured <sup>87</sup>Sr/<sup>86</sup>Sr were not more than 0.5 per cent for <sup>87</sup>Rb and 0.05 per cent for the <sup>86</sup>Sr tail, and averaged a few tenths of 1 per cent for normalization to a standard <sup>87</sup>Sr/<sup>86</sup>Sr value of 0.1194.

The observed variance in normalized <sup>87</sup>Sr/<sup>86</sup>Sr under these conditions is about 6.5 × 10<sup>-6</sup> from eight comparisons with magnetically switched ratios measured on identical samples with a 6-in. 90° sector mass spectrometer. This indicates that a single <sup>87</sup>Sr/<sup>86</sup>Sr measurement on an unknown sample will fall within ± 0.0006 of the true value at the 95 per cent confidence level. Voltage-switched measurements on the Eimer and Amend standard SrCO<sub>3</sub>, which averages 0.7082 for <sup>87</sup>Sr/<sup>86</sup>Sr, give a comparable estimate of variance based on a small number of independent analyses; additional measurements are now in progress. Because the rocks analysed are so young no age correction has to be made to the measured <sup>87</sup>Sr/<sup>86</sup>Sr values.

Rubidium was determined by isotope dilution and potassium was measured by flame photometry after the method of Cooper<sup>19</sup>. The precision of both rubidium and potassium measurements is better than ± 1 per cent at the 95 per cent confidence level, and the accuracy is regarded as better than 2 per cent. Data are given in Table 1, and localities of the samples are given in the Appendix.

The measured <sup>87</sup>Sr/<sup>86</sup>Sr values for the samples from Réunion fall within the extremely narrow range 0.7040-0.7046, and average 0.7044. These values are experimentally indistinguishable from one another; there is no difference between the <sup>87</sup>Sr/<sup>86</sup>Sr for rocks from Piton des Neiges compared with Piton de la Fournaise. This remarkably low range in <sup>87</sup>Sr/<sup>86</sup>Sr indicates that the

Table 1. POTASSIUM AND RUBIDIUM CONCENTRATIONS AND THE ISOTOPIC COMPOSITION OF STRONTIUM IN ROCKS FROM RÉUNION AND RODRIGUEZ

Sample No. (GA)	<sup>87</sup> Sr/ <sup>86</sup> Sr	K (%)	Rb (p.p.m.)	K/Rb	Rock type and locality
1255	0.7044	0.675	14.6	462	Olivine basalt (tholeiite) Grande Montagne
1256	0.7041				
1256	0.7046	0.614	19.9	443	Olivine basalt (tholeiite) Grande Montagne
1261	0.7044	0.641	16.4	391	Olivine basalt (tholeiite) St. Denis
1257	0.7042	1.445	41.3	350	Alkali andesite, Le Bois de Neiges
1260	0.7044	1.943	59.6	326	Alkali andesite, Ravine de la Fontaine
1264	0.7044	1.559	49.7	320	Alkali andesite, Belouve
1266	0.7046	3.909	106.6	370	Syenite, la Chapelle
1266	0.7046	0.785	23.5	334	Olivine basalt, Riv. des Remparts
1263	0.7040	0.389	9.0	343	Picrite basalt, Grand Brûlé
1267	0.7046	1.205	35.2	343	Alkali basalt
1263	0.7039	1.096	36.8	298	Alkali basalt
1264	0.7040				

source region of all these rocks was very homogeneous in its <sup>87</sup>Sr abundance. It implies a close genetic relationship between the basalts and alkali andesites, and it is consistent with the view that the later alkali lavas were produced by fractionation of tholeiitic magma.

The samples analysed show a wide range in bulk chemical composition; for example, silica is less than 50 per cent and probably about 47 per cent for the basalts, and even lower for the picrite basalt, whereas the syenite has 64 per cent silica<sup>14</sup>. Thus, at least for the range of samples analysed, there is no evidence in Réunion for a change in the <sup>87</sup>Sr/<sup>86</sup>Sr with bulk composition as found by Leeming and Catanzaro<sup>8</sup> and Hamilton<sup>10</sup> in Hawaii and by Gast *et al.*<sup>9</sup> for volcanic rocks from Gough and Ascension Islands.

The two alkali basalts from Rodriguez have <sup>87</sup>Sr/<sup>86</sup>Sr values of 0.7039 and 0.7040, and have measured silica contents of about 47 per cent.

The <sup>87</sup>Sr/<sup>86</sup>Sr values for the Réunion and Rodriguez rocks lie in the middle of the observed range of 0.702–0.706 for this parameter for essentially all oceanic volcanic rocks that have been analysed. That there are real local and regional variations in <sup>87</sup>Sr/<sup>86</sup>Sr within this narrow range of values, and rarely beyond, has been demonstrated<sup>8</sup>, and this provides evidence for inhomogeneity in the strontium isotope composition of the oceanic upper mantle. In the context of the restricted area sampled for the present study there is no evidence for local variations in the strontium isotope composition. Gast *et al.*<sup>9</sup> showed that the isotopic composition of lead is a much more sensitive indicator of variation in the source regions, and it is planned to undertake such measurements on the rocks used in this investigation in the near future.

Because of the similarity in ionic charge and electro-negativity of potassium and rubidium these elements form a coherent geochemical pair. Some enrichment in rubidium relative to potassium may occur with magmatic differentiation owing to the larger size of the rubidium ion<sup>21</sup>.

In the Réunion samples there is a tendency for the K/Rb ratio to decrease with increasing potassium content. The two older basalts from Piton des Neiges have ratios of 450, and the younger basalt (1261), of comparable potassium content, gives a somewhat lower value of 390. The basalt and picrite basalt from Piton de la Fournaise, which respectively have higher and lower potassium contents than the Piton des Neiges basalts, yield K/Rb values of about 340. Hence, there appears to be an indication of a real difference between the lavas from the two volcanoes. The three alkali andesites from Piton des Neiges show K/Rb ratios of between 350 and 320, which are considerably lower than those found for the basalts from this volcano. The two alkali basalts from Rodriguez have K/Rb values of 300–340.

Except for the two older basalts from Piton des Neiges the measured K/Rb ratios on samples from Réunion are all lower than those reported<sup>8</sup> for rather similar lavas from Hawaii, where an average of about 510 was found for rocks with a potassium content of less than 2 per cent. However, the values of between 300 and 350 are similar to the K/Rb ratios reported for average crustal and oceanic basaltic rocks<sup>1,19</sup>.

The K/Rb ratio of 370 for the syenite from Piton des Neiges is high compared with the alkali andesites from this volcano, even though the potassium content is over a factor of two greater. This indicates impoverishment of rubidium relative to potassium; such behaviour seems to be characteristic of syenites and may be related to restricted entry of rubidium into the sodium-rich alkali feldspar of these rocks<sup>21,22</sup>.

We thank Dr. B. G. J. Upton and Dr. W. J. Wadsworth for their advice and R. Fannucci and E. Hugot for assistance while one of us was in Réunion. M. J. Vernon carried out the rubidium and strontium chemistry and J. A. Cooper made the potassium measurements. We also thank Dr. K. S. Heier for his advice.

## STRENGTH OF ALUMINIUM NITRIDE WHISKERS

By D. T. J. DAVIES and DR. P. E. EVANS

Department of Metallurgy, Manchester College of Science and Technology

ANALYSIS of the strength of materials, from an atomistic point of view, predicts that the ratio,  $\alpha$ , of fracture stress ( $\sigma$ ) to initial strain ( $\epsilon$ ) in atomic bonds will be of the order of 10 per cent  $E$  ( $E$  = Young's modulus). A value of  $\alpha$  of this magnitude should be obtainable for perfect crystals. Whereas in practice yielding occurs in high-strength structural materials when  $\alpha$  is about 1 per cent  $E$ , it has been known for a long time that whiskers or fibres of almost all materials, with diameters of  $\sim 10^{-4}$  cm, and large length/diameter ratios show values of  $\alpha$  near to the ideal value. Non-metallic whiskers having mixed ionic/covalent bonding with low specific densities and high melting-points have been examined as strengthening media for fibre-reinforced materials<sup>1</sup>. Analysis of fibre-reinforced systems have recently been made by Cottrell<sup>2</sup> and Kelly<sup>3</sup>.

Aluminium nitride is a refractory material which may be considered suitable as a fibre-reinforcing material. Whiskers of this material were prepared by heating aluminium nitride powder (contained in an alumina crucible), at temperatures up to 1,820°C in an alumina tube in a flowing atmosphere of high-purity nitrogen diluted with high-purity argon. Chemical and X-ray analysis of the whisker product confirmed that the whiskers were aluminium nitride. The whiskers formed on cooler sections of the container. It is suggested that the whiskers grow by a process of dissociation of aluminium nitride powder at the operating temperature with subsequent growth of whiskers, from a vapour phase, at a cooler substrate. Straight whiskers, about 18–20 mm long, were formed after 15 h at temperature, giving an average growth rate of about 1.5 mm/h. Some of the whiskers with good morphological symmetry had 'kinks' and 'branches' (Fig. 1) and it was also observed that a whisker changed its axial growth direction by about 2° (minimum) to 20° (maximum) over its length. Platelets formed at slightly higher temperatures showed surface striations (Fig. 2); under oblique illumination these striations appeared to be

growth steps and not slip planes perpendicular to the major growth axis. The results of bend and tensile strength determinations on whiskers are given in Tables 1 and 2.

**Bend-strength tests.** The whiskers were subjected to bending on a Reichart microscope stage. Fig. 3 shows a typical bend in a whisker before fracture. All these tests were conducted with the whisker lying in a film of oil.

For perfectly elastic bending, the tensile stress in the outer surface of a fibre can be expressed as:

$$\sigma = \frac{Er}{p}$$

where  $\sigma$  = tensile stress in outer fibre;  $E$  = Young's modulus;  $r$  = radius of fibre;  $p$  = radius of curvature. It was observed that fracture occurred most frequently in whiskers containing common types of structural imperfections, that is, low-angle kinks, whiskers with twists of about 10° along their length and whiskers with surface growth steps.

The majority of whiskers were extremely flexible and it was sometimes difficult to obtain a sufficiently small

Fig. 2

Fig. 3

Table 1. BEND STRENGTH OF ALUMINIUM NITRIDE WHISKERS ( $E = 50 \times 10^4$  lb./in.<sup>2</sup>)

No.	Length ( $\mu \times 10^3$ )	Cross-section ( $\mu$ )	$p$ ( $\mu$ )	$\sigma = \frac{Er}{p}$ (lb./in. <sup>2</sup> )	$\frac{\sigma}{E}$ (%)
1	7.3	2.5 × 4.0	60	1.04 × 10 <sup>4</sup>	2.08
2	4.2	2.5 × 3.0	58	1.08 × 10 <sup>4</sup>	2.16
3	5.0	2.8 × 3.5	72	0.97 × 10 <sup>4</sup>	1.93
4	7.5	7.2 (hex)	1,820	9.9 × 10 <sup>4</sup>	0.02
5	5.2	6.5 (hex)	1,720	9.5 × 10 <sup>4</sup>	0.19
6	5.0	5.5 (hex)	1,900	7.25 × 10 <sup>4</sup>	0.03
7	8.2	3.0 × 8.0	75	1.0 × 10 <sup>4</sup>	2.00
8	8.3	8.0 × 10 <sup>3</sup> × 2.5 × 10 <sup>3</sup> (platelet)	10 <sup>4</sup>	1.25 × 10 <sup>4</sup>	—
9	4.7	3.5 × 2.5	78	0.8 × 10 <sup>4</sup>	1.60
10	4.2	3.7 × 2.3	82	0.88 × 10 <sup>4</sup>	1.75
11	5.0	4.0 × 2.2	2,500	2.2 × 10 <sup>4</sup>	—
12	5.2	8.0 × 2.5	10 <sup>4</sup>	6.7 × 10 <sup>4</sup>	—

All specimens except No. 6 were immersed in oil during testing. All specimens except Nos. 11 and 12 were bent about an axis parallel to the longest side of the cross-section; Nos. 11 and 12 were bent about the shorter cross-sectional axis. Specimens 4, 5 and 6 were produced in the image furnace<sup>4</sup>; for these specimens with a hexagonal cross-section the mean diameter is given.

Table 2. TENSILE MEASUREMENTS (GAUGE LENGTH 1.0 cm)

No.	Whisker section ( $\mu$ )	Load at fracture (g)	Fracture stress ( $\sigma$ ) (per lb./in. <sup>2</sup> )
1	10 × 38	272	1.02 × 10 <sup>4</sup>
2	17 × 22	188	0.72 × 10 <sup>4</sup>
3	9 × 42	260	0.68 × 10 <sup>4</sup>
4	11 × 37	268	0.94 × 10 <sup>4</sup>
5	10 × 39	272	0.99 × 10 <sup>4</sup>
6	8 × 45	268	1.06 × 10 <sup>4</sup>
7	26.3 mean diam. (hex)	52	0.14 × 10 <sup>4</sup>
8	28.6 mean diam. (hex)	53	0.18 × 10 <sup>4</sup>

radius of curvature to induce fracture. Where fracture did not occur the bent whiskers reverted to the initial shape when the constraint was removed. The results of bend tests on whiskers of different cross-section are given in Table 1.

From direct observations of the whiskers during bending and from the results of Table 1 it was concluded that:

(a) The maximum strength and flexibility were associated with whiskers of small cross-section and large length:diameter ratios. These whiskers also possessed smooth and apparently defect-free surfaces.

(b) Whiskers with an hexagonal cross-section had poor strength.

(c) When the bending moment was applied on the shortest side of a whisker section the whisker showed low strength.

(d) The presence of an oil film appeared to improve the strength of the whiskers, possibly by reducing the chance of surface damage.

(e) All whiskers fractured within the elastic limit.

**Tensile testing.** The tensile strength of whiskers was measured with an 'Instron' tensile testing machine with a load cell giving full-scale deflection for 400 g. The whiskers were mounted on a reinforced cardboard holder with an accurately punched gauge length of 1 cm. Some of the

whiskers tested had a taper of about  $2^\circ$  over the gauge-length; for these the cross-sectional area was taken as the average of the minimum and maximum measured. Although more than 50 specimens were mounted and tested, only 8 of these fractured within the gauge-length; a large percentage of fractures occurred at the base of the mounting resin. The results are given in Table 2.

All fractures occurred without plastic deformation taking place. The fracture surfaces showed that all the fractures were conchoidal. The lower strength of the whiskers of hexagonal cross-section is not completely understood and, although these may contain axial voids, examination of the fracture surfaces did not reveal this phenomenon. Excluding specimen number 2, the mean value of the experimental tensile fracture stress of the first six specimens is  $1.0 \times 10^6$  lb./in.<sup>2</sup>, that is, about 2 per cent  $E$ . Transmission electron microscope examination of a large number of thin whiskers and platelets has not, so far, provided conclusive evidence of the presence of dislocation.

## OPENING ELECTRICAL CONTACT: BOILING METAL OR HIGH-DENSITY PLASMA?

By PROF. F. LLEWELLYN JONES, C.B.E.\*, and M. J. PRICE

Department of Physics, University College of Swansea, University of Wales

THE processes occurring at the opening of a low-voltage ( $\sim 4$  V) electrical contact have considerable fundamental physical interest as well as having practical importance in the field of electronic and communication engineering. It is well known<sup>1</sup> that, starting with the electrodes closely pressed together in the fully closed position, the opening process leads to a constriction of the current stream lines, which can produce intense local heating and melting of the penultimate microscopic region of contact. The maximum temperature in the contact is related to the potential difference by the  $\psi$ ,  $\theta$  theorem:

$$\psi = \left[ 2 \int_0^{\theta_m} \frac{\lambda}{x} d\theta \right]^{1/2} \quad (1)$$

where  $\psi$  = a generalized potential equal to the electrical potential in the absence of thermo-electric effects,  $\theta$  = temperature,  $\lambda$  = thermal conductivity and  $x$  = electrical conductivity. Thus, on gradual separation of the electrodes the constriction resistance increases and the temperature rises up to and past the melting-point of the metal. On continuing the withdrawal the molten volume thus increases and gets drawn out into a microscopic bridge of molten metal joining the solid electrodes; the contacts finally separate and the circuit opens only when this bridge is broken. The rupture process, however, can be very complicated and lead to transfer of metal from one electrode to the other, a process which, when continually repeated, can lead to the 'pip' and 'crater' formation which renders the contacts useless after some time. There is evidence<sup>1,2</sup> to show that the matter transferred per operation ( $\sim 10^{-13}$  cm<sup>3</sup> in a 5-amp circuit) is related to the size of the molten metal bridge (width  $\sim 10^{-4}$  cm/amp), so that the stability, growth and final rupture of the bridge are a matter of importance,

not only from practical considerations, but also from the point of view of the physical properties of metals in the molten state and at high temperatures.

In the first place, an important condition of equilibrium, at least in the earlier stages, is that which depends on the application of surface tension forces. The shapes of the bridges would then be surfaces of revolution satisfying the equation:

$$\Delta p = T \left( \frac{1}{R_1} + \frac{1}{R_2} \right) \quad (2)$$

and these are unduloids, catenoids or nodoids according as  $\Delta p$  is positive, zero or negative respectively<sup>3</sup>. Photographs of static microscopic bridges have indeed confirmed that these stable shapes can be attained<sup>1</sup>. In the later stages of opening  $\Delta p$  will be negative, and experiment has established that the final stable shape is usually the nodoid. The  $\psi$ ,  $\theta$  theorem shows that the hottest region of the microscopic molten metal bridge between like electrodes will probably be the narrow neck and, at first sight, it might appear that this is the region at which the bridge is most likely to break. However, detailed investigation of this final process raises some important problems in the physics of metals at high temperatures, and, in particular, near their boiling points.

### Mechanisms of Break

It can be seen at once from the  $\psi$ ,  $\theta$  theorem that the mechanism of rupture of the molten metal bridge involves the physical properties of the metal, not at any one temperature, but over a wide range of temperatures up to boiling-point, and a number of different processes of rupture are possible.

In the first place, continued separation of the electrodes and the drawing out of the bridge increases the contact resistance  $R_c$ ; consequently, the contact voltage  $V_c$  ( $= R_c I_c$ ) for a given circuit current  $I_c$  continually rises.

\* Present address: Scientific Research Council, Radio and Space Research Station, Datchet, Buckinghamshire.

Inspection of the  $\psi$ ,  $\theta$  theorem shows that the maximum temperature  $\theta_m$  correspondingly increases; in fact, it is readily seen by using the Wiedemann-Franz law that, when  $V_s$  exceeds about 1.5 V, the corresponding value of  $\theta_m$  from (1) exceeds the boiling-point of any known metal. Thus, this process of rise of maximum temperature may well continue until  $\theta_m$  reaches the boiling point  $\theta_b$  so breaking the molten metal bridge. The voltage  $V_s$  at which this occurs is called the boiling voltage, and is related to  $\theta_b$  by equation (1). Further analysis of the  $\psi$ ,  $\theta$  theorem shows that, since the relationship between  $\psi$  and  $\theta$  depends on the variation of  $\lambda/\kappa$  with  $\theta$ , thermal instability can occur for certain functional relationships of  $\lambda/\kappa$  with  $\theta$ , in which case a sudden rise of  $\theta_m$  up to the boiling point can, in certain circumstances, take place. Measurements of the contact current, potential difference and maximum temperature, and its location, enable a determination to be made of the transport properties of metals such as their thermal and electrical conductivities and Thomson coefficients and their dependence on temperature to be determined for the molten state at high temperatures<sup>1</sup>.

These thermal effects, however, are not the only processes which may sever the bridge. For example, the electromagnetic pinch effect might well, with large currents, so constrict the bridge at the narrowest, hottest and therefore weakest point as to rupture it there. Again, the known variation of surface tension with temperature is an important factor influencing the stability of the bridge, and the consequences of this can only be neutralized by the influence of surface impurities or compensating internal viscous motions in the bridge. Restriction due to the size and geometry of the actual electrodes in a given practical contact might well prevent the continued formation of the stable nodoid form, and instability could result.

The shape and volume of the final bridge and its mechanism of rupture are very important from the practical point of view on account of their relation to the rate of matter transfer on rupture. For example, suppose that a thermo-electric effect displaced the hottest section of the molten metal bridge towards one electrode, then it follows that the rupture at that particular section could have the effect of producing net transfer from one electrode to the other. The amount transferred may then only be that of the hottest region in the neck. On the other hand, if, in a different process of rupture, the molten metal bridge disintegrated as a whole and was transferred to one or other electrode (say, by mechanical splashing of minute droplets), then in this case the matter transfer could be relatively high and this, of course, could have serious practical effects.

Thus, the precise processes of the actual opening of the circuit are a matter of considerable practical and theoretical importance, and these phenomena have been under investigation at Swansea for some time. The relationships of the size of the molten metal bridge to the current and to the matter transferred per operation and the local self-inductance have been investigated<sup>1,2-10</sup>.

Accurate measurement of the amount of metal of a given electrode ( $\sim 10^{-12}$  g) actually transferred on the rupture of the molten metal bridge was found possible using the radioactive tracer technique, and a very rapid variation with local inductance, particularly in the range  $10^{-8}$  to  $10^{-3}$  H, was found for a number of metals and, particularly so, for platinum<sup>1,2-4</sup>. Further, optical examination of the crater formed on bridge rupture indicated that in some metals the whole volume of the molten metal bridge took part in the transfer. The shape and volume of the microscopic bridge were determined from the geometry of the melting isothermals in each electrode after rupture.

Facts such as these are difficult to reconcile with the picture of matter transfer occurring as the result of a mechanical splashing of small droplets formed from the disintegrating molten metal bridge. On the contrary,

Fig. 1

Fig. 2

Fig. 3

Fig. 1. Material, iron; atmosphere, air; current, 30 amp; circuit R.M.F., 6 V; polarity, top electrode negative; magnification,  $\times 6$ ; framing rate, 6,000 f.p.s.

Fig. 2. Material, iron; atmosphere, air; current, 30 amp; circuit R.M.F., 6 V; polarity, top electrode negative; magnification,  $\times 6$ ; framing rate, 2,000 f.p.s.

Fig. 3. Material, iron; atmosphere, vacuum; current, 60 amp; circuit R.M.F., 6 V; polarity, top electrode positive; magnification,  $\times 19.5$ ; framing rate, 7,000 f.p.s.

they are more consistent with the view that the transfer may well be ionic, the motions of the ions being determined by the oscillatory electric field between the electrodes after the bridge has broken. For reasons such as these an alternative view was put forward based on the production of a micro-plasma, possibly initially formed at the broken neck of the molten metal bridge<sup>11</sup>. Consequently, in recent years effort has been directed to finding direct evidence for the existence of such a plasma. It will be appreciated that, owing to the speed of events in the final stages of the development of the molten metal bridge, extensive expansion of the plasma to a size which can readily be seen may not take place. In fact, particularly in the presence of a high-pressure ambient atmosphere, a plasma of metal vapour might well be severely restricted in size throughout its short life.

#### Photography of the Microscopic Molten Metal Bridge

Early attempts to photograph the development of the exploding bridge were confined to cases in which it would be expected that surface tension would be the dominant controlling force and large stable bridges obtainable. Such photographs have been previously obtained for large iron bridges in air<sup>1</sup>. In appropriate circumstances the oxide film on the surface would enable a constant surface

tension to be set up over the whole surface, and thus produce stability in accordance with (2).

A number of standard ciné films (25 f.p.s.) were taken of the formation, development and final rupture of the bridge, and many thousands of frames were examined in the hope of finding an illustration of the actual rupture. One or two frames were found which showed that the actual rupture process might not be a simple parting of the nodoid, and this indicated that it was necessary to use high-speed photography if rupture was to be examined in more detail. There were considerable difficulties in the high-speed photography of the molten bridge mainly on account of the small area to be photographed ( $\leq 10^{-4}$  cm<sup>2</sup>), the low luminosity for metals other than platinum and tungsten, and the difficulty associated with the synchronization of the camera and the phenomenon to be photographed. A certain degree of elusiveness of the bridge at all stages of its life also made photography difficult. However, an optical system incorporating a high-speed camera was designed and constructed to examine the development of a molten metal bridge for time-intervals down to about 10  $\mu$ sec. In this way a large number of metals were investigated under varying conditions of ambient atmosphere and pressure. Some preliminary photographs thus obtained were shown at conferences at Oklahoma<sup>1</sup>, at Graz<sup>2</sup> and at Berlin<sup>3</sup>. Sets of later photographs giving a succession of frames extending over a total time of a few milliseconds covering in some detail various phases of the rupture of the microscopic molten metal bridge are given here. The results for iron are of particular interest in that they illustrate the three different aspects of the rupture process discussed here, and these are given in Figs. 1, 2 and 3.

Fig. 1 shows a series of photographs at a rate of 10<sup>4</sup> frames per sec and deals with iron in air. Doubtless on account of consequent oxidation affecting the surface tension, well-shaped stable bridges were formed after a number of operations, and these are in accordance with the theoretical prediction of the stable nodoid. Stability could be controlled by surface tension forces, and the fact that the bridge ruptured when the hottest section boiled is clearly indicated by the photographs, which show the two white-hot separate parts of the bridge after rupture.

Fig. 2 illustrates a less stable condition in which the degree of oxidation was such that the surface tension could not be maintained constant over the surface. In such cases stability can only be produced by internal viscous motion, and this is consistent with the effect illustrated

by the rapid change from frame to frame in the location of the hottest region of the bridge surface.

In order to minimize the effect of surface tension forces in establishing stability, the iron surfaces were cleaned by a glow-discharge treatment in hydrogen and the contact was also operated in a vacuum in order to avoid further oxidation. The development of the bridge in this case is illustrated by the series in Fig. 3. This is dramatically different from the two series in Figs. 1 and 2 in that the molten metal bridge no longer severs over a very small section while the bridge remains in the liquid form. On the contrary, in this case an electric micro-discharge appears to have been formed from the completely exploded bridge, producing a high-density plasma of great brightness the duration of which is less than 100  $\mu$ sec and probably less than 10  $\mu$ sec. On account of the inability to expand appreciably in these conditions, the particle density in the micro-plasma must be extremely high.

Similar effects have been found for other metals, and the radio-tracer technique enables the directions of the metallic transfer occurring during this short existence of the plasma to be measured.

We thank Mr. Ieuan Maddock of the Atomic Weapons Research Establishment, U.K. Atomic Energy Authority, Aldermaston, for the loan of a high-speed camera and for advice. One of us (M. J. P.) is also grateful for the award of a Department of Scientific and Industrial Research postgraduate research studentship. Thanks are also due to the Royal Society for a grant for the purchase of precious metals.

## BASAL PLANE CONTRACTION IN GRAPHITE DUE TO MONO-VACANCIES

By B. T. KELLY

United Kingdom Atomic Energy Authority, Reactor Materials Laboratory, Culcheth, Warrington, Lancashire

IT has been known for a number of years that crystals of graphite expand along the c-axis direction and contract along the a-axis direction under fast neutron irradiation. The dimensional changes of the c- and a-axis lattice parameters have been observed by X-ray diffraction<sup>1,2</sup> and it is found that the fractional change  $\Delta c/c$  in the c-axis lattice parameter is positive and the fractional change  $\Delta a/a$  in the a-axis lattice parameter is negative. Direct measurements<sup>3,4</sup> of the dimensional changes of graphite crystals and deductions from irradiation data on polycrystalline graphite have shown that the strains  $\epsilon_c$  and  $\epsilon_a$  in the c-axis and a-axis direction of a graphite crystal either exceed or are equal to the lattice parameter changes.

The growth of the crystals in the c-axis direction is explained by the presence of interstitial atoms between the crystal layer planes. The inequality between  $\epsilon_c$  and  $\Delta c/c$  has been explained by Simmons and Reynolds<sup>5</sup> as due to

the aggregation of these interstitial atoms into small new layer planes which contribute to crystal growth but not, of course, to lattice parameter changes. The c-axis growth of the crystal may be expressed in terms of the interstitial atom concentration  $C_i$  as:

$$\epsilon_c = KC_i \quad (1)$$

The constant  $K$  is of order unity, tending to decrease to a limit of unity with increasing aggregation of the interstitial atoms into areas of new layer plane.

The contraction in the a-axis lattice parameter and the basal plane contraction  $\epsilon_a$  have been the subject of some speculation. It has at various times been proposed that the decrease in the a-axis lattice parameter may be explained as follows:

1. Elastic relaxation around the vacant lattice site; however, the extremely tight covalent binding of the layer suggests that this would be a small effect.

2. A Poisson's ratio effect accompanying the *c*-axis lattice parameter change. This follows from the negative thermal expansion coefficient along the basal planes observed by Nelson and Riley<sup>4</sup> and attributed to the same mechanism. The magnitude of this effect is easily shown to be:

$$\frac{\Delta a}{a} = \frac{S_{12}}{S_{33}} \left( \frac{\Delta c}{c} \right) \quad (2)$$

It is shown later that this alone is not adequate to explain experimental data.

3. A buckling of the lattice by interstitial clusters, this being observed as an apparent decrease in lattice parameter.

It is proposed in this note that the major contribution to basal plane contraction is due to the modification of the interatomic linkages in the layer by the presence of the vacancy.

The lengths of the basic C—C and C=C bonds are known to be 1.542 Å and 1.334 Å respectively<sup>5</sup>, whereas the bond length in graphite lies between these values (1.416 Å). This is interpreted by assuming that a partial bond is formed between nearest neighbours by the  $\pi$ -electrons in graphite, as well as the bond formed by the  $\sigma$ -electrons. Coulson<sup>6</sup> has shown that a bond order may be defined in terms of molecular orbital calculations of the electronic structure of molecules which may be used to predict bond lengths accurately. In particular, the interatomic distance in graphite has been predicted by Bradburn, Coulson and Rushbrooke<sup>6</sup>. Table 1 shows the bond-length change relative to graphite as a function of bond order. Coulson<sup>6</sup> shows that the bond length *a* as a function of bond order *P* is given by:

$$a = 1.542 - \left[ \frac{0.298}{1 + 0.765 \left( \frac{-P}{P-1} \right)} \right] \text{Å} \quad (3)$$

The molecular orbital method has recently been applied by Coulson and co-workers<sup>10</sup> to the calculation of the change in  $\pi$ -electron energy of graphite layers of various sizes on removal of one atom (including its  $\pi$ -electron). If the layer contains *n* atoms, then the change  $E$  in the  $\pi$ -electron energy of the molecule is given by:

$$\Delta E_{\pi} = \left[ \frac{n}{0.363n - 0.548} \right] \beta \quad (4)$$

where  $\beta$  is the resonance integral<sup>6</sup>.

It is now postulated that the basal plane contraction is due to the changes in the bond order of the layer due to the formation of a vacancy. The magnitude of this effect may be estimated as follows:

Consider a uniformly distributed concentration of vacancies  $C_v$  in an infinite graphite layer, then each vacancy has associated with it *n* atoms where  $n = 1/C_v$ . If a 'molecule' of the type considered by Coulson *et al.* is drawn around each vacancy containing *n* atoms, then the change in  $\pi$ -electron energy of the molecule is:

$$\Delta E_{\pi} = \left[ \frac{1}{0.363 - 0.548 C_v} \right] \beta \quad (5)$$

The bond order is given by Coulson *et al.* for the graphite layer as:

$$P = 1 + \frac{E_{\pi}}{2B\beta} \quad (6)$$

Table 1. BOND LENGTH CHANGES RELATIVE TO GRAPHITE AS A FUNCTION OF BOND ORDER

Bond	Bond order	Bond length	Length change relative to graphite %
Ethane C—C	1	1.542	+ 8.9
O—O*	1	1.504	+ 6.2
Ethylene C=C	2	1.334	- 5.8
Acetylene C≡C	3	1.206	-14.8

\* Value given by Pauling<sup>5</sup> for use in conjugated and aromatic systems.

where *B* is the number of bonds in the molecule. The change in bond order assuming all unbroken bonds to be equivalent is:

$$\Delta P = \frac{1}{2\beta} \left[ \frac{E_{\pi}^1}{B^1} - \frac{E_{\pi}}{B} \right] \quad (7)$$

where  $B^1 = B - 3$  is the number of unbroken bonds in the 'molecule',  $E_{\pi}^1$  is the  $\pi$ -electron energy of the molecule. Provided  $C_v$  is not too large we may set  $B = B^1$  and thus:

$$\Delta P = \frac{\Delta E_{\pi}}{2\beta B} \quad (8)$$

The 'average' bond-order of the remaining bonds is now given by:

$$P = 1.525 + \Delta P = 1.525 + \frac{1}{2} \left[ \frac{C_v}{(0.363 - 0.548 C_v) 1.500} \right] \quad (9)$$

(1.525 is the calculated bond order of the normal C—C bond in the layer plane).

The change in average bond length of the layer may now be estimated using equation (3) and equation (9). It is found that for a vacancy concentration of up to 5 per cent the length change, which we assume equal to the observed lattice parameter changes,  $\Delta a/a$ , can be represented by:

$$\frac{\Delta a}{a} = -0.14 C_v \quad (10)$$

The presence of an increase  $\Delta c/c$  in *c*-spacing gives a further contraction due to the Poisson effect, thus:

$$\frac{\Delta a}{a} = \frac{S_{12}}{S_{33}} \frac{\Delta c}{c} - 0.14 C_v \quad (11)$$

The values of  $S_{12}$  and  $S_{33}$  given by Davidson and Losty<sup>11</sup> lead to  $S_{12}/S_{33} = -0.07$ .

The principal characteristics of the mechanisms of basal plane contraction discussed here are: (a) The X-ray lattice parameter change  $\Delta a/a$  should agree with the directly measured basal plane contraction, that is  $\epsilon_a \equiv \Delta a/a$ . The same considerations apply to clusters of a few vacancies. (b) The effect of the same total number of vacancies on both lattice parameter and  $\epsilon_a$  will decrease as they aggregate into larger and larger clusters. In the extreme case a large disk-like hole in a layer plane produces no basal plane contraction and no lattice parameter changes. The collapse of this type of cluster gives a *c*-axis contraction of the crystal.

Equation (11) may be compared with direct measurements of basal plane contraction if independent estimates of  $C_v$  and  $\Delta a/a$  are available.

Pluchery<sup>12</sup> has irradiated graphite with reactor neutrons at  $-196^\circ\text{C}$  at which temperature both interstitial atoms and vacancies are immobile. In these conditions no defect aggregation should have occurred at low doses and the interstitial and vacancy concentrations should be equal; it is thus reasonable to assume that  $\epsilon_c \equiv \Delta c/c$ , and  $\epsilon_a \equiv \Delta a/a$ . Using equation (11) for this case we can write:

$$\begin{aligned} \frac{\Delta a/a}{\Delta c/c} &= \frac{S_{12}}{S_{33}} - \frac{0.14}{K} \\ &= -0.07 - \frac{0.14}{K} \end{aligned} \quad (12)$$

where *K* is the value for single interstitial atoms and is expected to be greater than unity. The experimental value taken from Pluchery's data is  $\frac{\Delta a/a}{\Delta c/c} = -0.08$ , thus suggesting that  $K \sim 10$ . The *c*-spacing change due to interstitial atoms has been calculated by Agranovich and Semenov<sup>13</sup> using interatomic potential functions of the spherically symmetric Lennard-Jones type with the constants adjusted to give the interlayer spacing correctly. This force function gives good agreement between theory and experimental determinations of compressibility and

surface energy. Their results yield  $\Delta c/c = 5.3 C_i$  in very reasonable agreement considering the approximations in the present calculation and the theoretical result.

A better comparison with experiment is obtained under conditions where  $K$  is close to unity—that is, where interstitial atoms, but not vacancies, have been allowed to cluster. This condition is realized for small doses where the vacancies are randomly distributed and essentially single at temperatures from about 150° to 350° C. However, although  $\epsilon_s \equiv \Delta a/a$  in these circumstances  $\epsilon_s \neq \Delta c/c$ . The homogeneous nucleation theory<sup>14</sup> suggests that the numbers of interstitial atoms and vacancies are still equal and thus equation (11) and equation (1) can be combined to give:

$$\frac{\Delta a/a}{\epsilon_s} = \frac{S_{11}}{S_{11} - \epsilon_s} \frac{\Delta c/c}{\epsilon_s} - \frac{0.14 C_i}{\epsilon_s}$$

$$= -0.07 \frac{\Delta c/c}{\epsilon_s} - 0.14 \text{ since } C_i = C_i \text{ and } \epsilon_s = C_i$$

In neutron irradiations at 200° C these conditions are fulfilled in Pile Grade A and pyrolytic graphites<sup>15</sup>, and  $\Delta c/c \sim 0.5$ , thus  $\frac{\Delta a/a}{\epsilon_s}$  is expected to be  $-0.17$ , while the observed value is  $-0.17$  in very good agreement. In irradiation experiments at 350° C for doses below  $5 \times 10^{18}$  neutrons per sq. cm (ref. 16),  $\epsilon_s \equiv \Delta a/a$  and an initial value of  $\frac{\Delta a/a}{\epsilon_s}$  of approximately  $-0.17$  is observed. In this case  $K \sim 1$  and the agreement is good.

It is clear from these considerations that the presence of interstitial atoms and single vacancies cannot if they are in equal numbers cause a value of  $-\epsilon_s/\epsilon_s$  in excess of about 0.2. The aggregation of vacancies into the expected type of cluster<sup>17</sup> would reduce  $\epsilon_s$ , and thus reduce the ratio  $-\epsilon_s/\epsilon_s$ , since  $K$  cannot be less than unity. A change of crystal shape, but not volume, corresponds to  $-\epsilon_s/\epsilon_s = 0.5$ , but for this to occur vacancies must be able to annihilate in some way without recombining with an

interstitial atom. It is interesting to note that this condition is approached under some irradiation conditions<sup>18</sup> where vacancies are comparatively immobile and where loss of interstitial atoms and vacancies to sinks can be ruled out. It is thus necessary to postulate new types of vacancy configuration to explain high dose results.

The results given here may be used to estimate the vacancy concentration after neutron irradiation and enable comparison to be made with determinations from other physical property changes. The accuracy of the factor 0.14 in equation (11) is expected to be quite good since the theoretical calculations of bond order are used with empirical information and the results do not rely on any uncertain parameter such as the resonance energy. This is discussed further by Coulson *et al.* in ref. 8.

I thank Prof. C. A. Coulson for his advice.

## ABNORMAL HAEMOGLOBINS AND THE GENETIC CODE

By D. BEALE and Dr. H. LEHMANN

Medical Research Council Abnormal Haemoglobin Research Unit, Department of Biochemistry, University of Cambridge

DR. F. H. C. CRICK has directed our attention to the latest work of Nirenberg *et al.*<sup>1</sup> which has considerably advanced the definition of the code whereby messenger RNA determines which amino-acid is incorporated into a protein. The code is 'degenerate' and more than one arrangement of three bases or a codon can spell the same amino-acid. The first two bases are, however, somewhat more specific than the third. For example, for glutamic acid (Glu) they are guanine adenine (GA), but the third can be either A or G. However, the first two bases in the codon spelling aspartic acid (Asp) are also GA, but the third may be cytosine or uracil (C or U). Thus the coding for Glu is GAA or GAG. Some amino-acids are coded by any of the four possible bases in the third place of the codon. For example, the coding for threonine (Thr) is ACA or G or C or U. For a few amino-acids only, alternatives have also been found for the first two bases of the codon: leucine (Leu), for example, may be coded UUA or G or as CUG or C or U. From the considerable evidence for A being an alternative third part of the codon when G is one, one might write the second coding for leucine as CUA or G or C or U. Table 1 gives the codons for amino-acids involved in substitutions of human haemoglobin; those surmised because A and G, and C and U, respectively, are alternatives in the third position, are in italics. Table 2 summarizes the amino-acid

substitutions which have been reported in human haemoglobin. They include the abnormal haemoglobins fully described and those for which an amino-acid substitution is known but has not yet been finally allocated to a definite part in one of the polypeptide chains. Furthermore, as the  $\beta$ - and  $\delta$ -polypeptide chains differ in only a very few amino-acid residues, likely to be point mutations, differences between these two chains have also been listed.

Fig. 1 illustrates the possible one-step mutations for the amino-acids listed in Table 2. This scheme covers all substitutions with one exception. As Dr. Crick has pointed out to us, haemoglobin I  $\alpha 16$  Lys  $\rightarrow$  Asp cannot have been the outcome of a single mutation but requires two muta-

Table 1. Messenger Ribonucleic-acid Codons for Amino-acids Involved in Substitutions in Human Haemoglobin

Lysine	AAA or G	Proline	CCA or G or C or U
Asparagine	AA	Leucine	GUA or G or C or U
Threonine	ACA or G or C or U		UUA or G
	AGA or G	Glutamic acid	GAA or G

Ala→Glu	β70 or β76, Seattle <sup>21</sup>	Pro→Gln	β120, A <sub>1</sub> <sup>19,36</sup>
Glu→Val	β6, S <sup>38</sup>		

Fig. 1. Possible one-step mutations for amino-acids involved in substitutions in human haemoglobin. The dotted lines indicate differences between  $\beta$ - and  $\delta$ -chains

tions within one codon. As this is a point of considerable theoretical interest we have re-investigated haemoglobin I and have found that, in fact, the substitution is  $\alpha 16$  Lys  $\rightarrow$  Glu. Thus, at present, all amino-acid substitutions in human haemoglobin can be the outcome of single mutations. Degeneracy of the code must be assumed because the last base in the codon for glycine cannot be the same for the mutations Glu  $\rightarrow$  Gly<sup>13</sup> and Gly  $\rightarrow$  Asp<sup>14-16</sup>; similarly, it cannot be the same for arginine in His  $\rightarrow$  Arg<sup>14</sup> and Gln  $\rightarrow$  Arg<sup>14</sup>. The exclusion of the step Lys  $\rightarrow$  Asp or Asp  $\rightarrow$  Lys as a single mutation strongly supports the formula involving  $\alpha 116$  Glu  $\rightarrow$  Lys for haemoglobin O Indonesia<sup>7</sup>. The electrophoretic mobility suggests a double charge change from an acidic to a basic residue. The peptide involved ( $\alpha T p X I I$ ) contains both, one Glu ( $\alpha 116$ ) and one Asp ( $\alpha 120$ ), but as Glu  $\rightarrow$  Arg, Asp  $\rightarrow$  Arg, and Asp  $\rightarrow$  Lys would require a double mutation the likely formula is  $\alpha_1 116$  Glu  $\rightarrow$  Lys<sup>39</sup>. By similar reasoning one can assume that haemoglobin Kenwood<sup>35</sup>, for which two alternative formulae involving  $\beta 143$  His  $\rightarrow$  Glu and  $\beta 143$  His  $\rightarrow$  Asp have been proposed, is likely to be  $\alpha_2 \beta_2 143$  His  $\rightarrow$  Asp.

So far as human haemoglobin is concerned, there are four possible charge changes detectable by electrophoresis at pH 8.6 (that is, a pH at which charge changes do not include the influence of histidine) (Fig. 2). A loss of a negative charge can arise from the replacement of Glu or Asp by a neutral residue, or from replacing a neutral residue by Lys or Arg. The variant of haemoglobin A will then move in the position of haemoglobins S or G. A positive charge can be lost by substitution of a Lys or Arg by a neutral residue or of a neutral residue by Glu or Asp. The resulting variants will then have the mobility of haemoglobins J or K. A double charge change involving either the replacement of a negative by a positive or of a positive by a negative charge can arise by a single mutation only when Glu is substituted by Lys, or Lys by Glu. Thus the haemoglobins C, E, O are all Glu  $\rightarrow$  Lys mutations, and the haemoglo-

bins of the I and N type must be expected to involve a change of Lys  $\rightarrow$  Glu.

It seems remarkable that of eleven glutamic acid residues, nine and possibly ten have been involved in mutations, three of them twice, yet of seventeen aspartic acid residues only one<sup>39</sup>, or possibly two<sup>39</sup>, have been subject to substitutions. On the other hand, changes to Asp and Glu occur with similar frequency, six and five times respectively. The genetic code would permit Glu and Asp to mutate equally well to Val, Ala, or Gly. In addition, whereas Glu can mutate to Lys and Gln, Asp can mutate to Asn, His or Tyr. All such mutations would involve charge changes in the molecule which would be detected by electrophoresis. The frequency of mutations from Glu to other residues and the rarity of replacements of Asp could suggest that Asp may be more important for the structure and function of the haemoglobin A molecule

Fig. 2. Paper electrophoresis at pH 8.6 of haemoglobin A, and four variants showing respectively one and two additional positive or negative charges per half molecule

Fig. 3. The 'fingerprint' of haemoglobin I. 1,  $\alpha 2 T p I I I$  missing; 2,  $\alpha 2 T p I V$  missing; 3, new peptide ( $\alpha 2 T p I I I - I V$ ); 4,  $\beta 2 T p V$ ; 5,  $\beta 2 T p V$  (oxidized). Note that the  $\beta 2 T p V$  peptides have the same electrophoretic mobility (horizontal) as the abnormal peptides from haemoglobin I, but they are well separated by chromatography (vertical)

# DECOMPOSITION OF CRYSTALLINE AMMONIUM NITRATE BY ULTRA-VIOLET LIGHT

By DR. T. W. ZAWIDZKI,\* DR. GIANNA L. PETRICONI and DR. HENRY M. PAPÉE

National Research Council of Italy, Centre for Aerosol Nucleation, Rome

**AMMONIUM** nitrate is an important industrial chemical, widely used in explosives and agricultural fertilizers. It decomposes exothermally in moderate heat, yielding mainly nitrous oxide and water, and it therefore presents some hazards during storage and transportation<sup>1</sup>, since it may explode as a result of a local overheating; this partly explains the continued recent interest in the mechanism of its thermal decomposition<sup>2-4</sup>. At the same time, both  $\text{NO}_2$  and  $\text{NH}_4^+$ , and hence ammonium nitrate, account for a substantial part of the atmospheric aerosol<sup>5,6</sup>, which is probably formed predominantly from atmospheric nitric acid and ammonia.

Decomposition of solid, inorganic, nitrates by ultra-violet light, with consequent formation of nitrite and oxygen, was qualitatively investigated in 1935 by Narayanaswamy<sup>7</sup> and, more recently, by Doigan and Davis<sup>8</sup>. Since no analyses of gaseous products resulting from photolysis of  $\text{NH}_4\text{NO}_3$  were carried out at that time the reaction was given further attention in this laboratory, and it was found that exposure of the pure, crystalline, salt to the light obtained from a high-pressure mercury ultra-violet lamp resulted in its superficial decomposition with the yield of  $\text{N}_2\text{O}$  and  $\text{H}_2\text{O}$ , as well as of nitrogen and oxygen.

Experiments were carried out in a tubular, horizontal quartz cell, 3.0 cm inside diameter and 14.0 cm effective length, which was heat-shielded by a quartz jacket cooled by an electric fan. The cell was half-filled with  $\text{NH}_4\text{NO}_3$  and was connected on one side to a high-vacuum and gas-volumetric assembly. The connexion was done through two traps, one of which was removable; interchangeable stoppered glass bulbs could be connected to the volumetric system, in order to take samples for mass-spectrographic analyses of the gaseous products. The quartz cell was provided with a stoppered inlet in order to permit experimentation at atmospheric pressure and in a current of nitrogen or air. The nitrogen gas used was of 99.99 per cent purity: both nitrogen and air were made to pass through a liquid oxygen trap before being admitted to the quartz cell. The flow of gas was constant and of about 20 l./h, as monitored by a wet-test meter (Precision Scientific Co.). A stabilized high-pressure mercury 550-W. 'Hanovia' ultra-violet lamp, model 673 A, was mounted on a rigid support above the cell and illuminated the surface of the salt with about  $16 \times 10^{11}$  quanta/cm<sup>2</sup>/h in the 2540-4350 Å region, as estimated by uranyl-oxalate actinometry<sup>9</sup> which was carried out in the same cell at the beginning and end of the project. Dry, reagent grade ammonium nitrate (Merck, 'as received') was used for the experimentation: the salt was desiccated in the experimental assembly for 48 h, in a vacuum obtained by a fast diffusion pump, before each photo-decomposition was initiated. Experiments were carried out under conditions described in Fig. 1; the oxygen and nitrogen evolved were volumetrically determined after condensing  $\text{H}_2\text{O}$ ,  $\text{N}_2\text{O}$ , etc., in the first trap, which was cooled with liquid nitrogen. This coolant was then replaced by a dry-ice and acetone bath, and the nitrous-oxide fraction (which contained some NO-impurities) was distilled under evacuation into the next trap which, at that time, was cooled with liquid nitrogen. The gases condensed in the second trap were then volumetrically determined and sampled for mass-spectrometry; this was followed by gravimetric determination of the liquid residue in the first trap and a semi-quantitative estimation of its content. All volumetric measurements were greatly simplified by maintain-

ing the room in which the experimental assembly was mounted at  $20.0^\circ \pm 0.5^\circ \text{C}$ .

Fig. 1 gives the total amounts of  $\text{N}_2\text{O}$  evolved with time under different conditions, while Fig. 2 gives a plot of nitrogen-oxygen mixtures evolved in a closed circuit assembly against the amount of nitrous oxide collected. Mass spectrographic analyses, carried out on six different samples of non-condensable gases evolved during this latter series of experiments, indicated a constant ratio of nitrogen to oxygen of  $5.1 \pm 0.1$ ; the NO-content of the nitrous-oxide fraction was found to be of the order of 4.0

Fig. 1. Plots of nitrous oxide evolved, with time, under the experimental conditions specified, and under irradiation of 48 cm<sup>2</sup> of ammonium nitrate surface with  $6.7 \times 10^{11}$  quanta in the range of 2540-4350 Å, per h. Top: ●, continuous evacuation; ▲, flow of dry air at atmospheric pressure. Bottom: ○, apparatus evacuated and closed; ▲, flow of nitrogen at atmospheric pressure.

Fig. 2. Ratio of nitrous oxide and NO impurities, to oxygen-nitrogen mixture evolved, with time, in a closed vessel.

Table 1. SUMMARY OF RESULTS OBTAINED UNDER DIFFERENT CONDITIONS OF PHOTOLYSIS OF SOLID AMMONIUM NITRATE

Conditions of experiment	Total time of irradiation (h)	$\frac{dN_2O}{dt}$ (moles/h $\times 10^4$ )	$\frac{N_2O}{N_2 + O_2}$ (moles)	Molar ratio, $H_2O : N_2O$ , developed during total irradiation	Analysed content of liquid residue, in moles $\times 10^4$		
					$NH_4^+$	$NO_2^-$	$NO_3^-$
Continuous evacuation	60.17	$5.6 \pm 0.06$	—	6.25	7.2	0.8	4.1
Assembly evacuated and closed	134.75	$5.9 \pm 0.03$	$2.8 \pm 0.02$	5.2	3.0	0.1	0
Flow of $N_2$ , atmospheric pressure	98.50	$4.4 \pm 0.04$	—	4.90	3.0	0.8	9.1
Flow of air, atmospheric pressure	89.18	$6.6 \pm 0.08$	—	4.96	6.6	0.1	4.6

Ten g of salt used, when dissolved in water, gave 1 l of solution at pH = 5.50; ultra-violet-irradiation of salt did not appear to change acidities of solutions prepared, appreciably. Liquid residues were at all times alkalinised with NaOH immediately after trap was opened. The experiment, which was carried out in a closed assembly, yielded, however, 0.38 g of liquid which gave, with water, 100 ml. of solution at pH = 3.0.

$\pm 2.0$  per cent. Water was estimated gravimetrically as total liquid residue;  $NO_2^-$ ,  $NH_4^+$  and  $NO_3^-$  were determined colorimetrically with brucin, Neesler and Griess reagents, respectively. Since, under our experimental conditions and during 3 days of continuous evacuation, we were unable to transfer, in a blank run, from the quartz cell into the trap at temperatures of liquid nitrogen, amounts of  $NH_4NO_3$  which could be colorimetrically detected by the Neesler reagent, it was assumed that the vapour pressure of this salt was low<sup>18</sup>, and that the bulk of the reaction occurred in the solid phase.

The differences between the rates obtained under the experimental conditions described, are probably due to products of reaction which contaminate the surface photolysed (compare with ref. 2). 'Contaminations' of the frozen water fraction are at their lowest in the series of experiments which were carried out in a closed circuit, possibly due to higher retention times of the gaseous products in the quartz cell. This may indicate that the impurities quoted and found in the water fraction originate from reactions occurring beyond the irradiation zone between free-radical species, with possible contribution of vapours of such compounds as nitramide and nitrosamine, which are thought to be precursors of  $N_2O$  and  $N_2$  in the thermal decomposition of  $NH_4NO_3$  (refs. 3, 11). It may, in fact, be of interest that since no hydrogen-peroxide could be found by the titanium sulphate test in the liquid fraction, the introduction of  $NH_2-NO$ , as one of the main products of the reaction, together with  $N_2O$ ,  $H_2O$ ,  $N_2$  and  $O_2$ , is convenient here in order to account for the material balance of the process expressed along the lines of the results contained in Table 1; although it is evident that some of the 'impurities' condensed in the water-fraction may originate directly from photolysis of  $N_2O$  in the near ultra-violet (compare with ref. 12).

Nitrous oxide is known to be present in the Earth's atmosphere<sup>13,14</sup>; and it was hitherto thought to originate

either from  $N_2$  and oxygen atoms derived from ozone, as shown by Harteck and Dondes<sup>15</sup>, or through the action of short ultra-violet light on nitrogen and oxygen mixtures, as discovered by Groth and Schierholz<sup>16</sup>, or else, apparently, by bacteria of the soil<sup>17</sup>. The present contribution strongly indicates that photolysis of atmospheric ammonium nitrate aerosol may contribute to the formation of atmospheric  $N_2O$ , and that ultra-violet light may partly account for the decomposition of the  $NH_4NO_3$ -component of the natural aerosol, and hence reduce its power as 'atmospheric fertilizer'.

We thank Dr. G. G. Volpi, and his collaborators at the University of Rome, for the gas analyses, which were carried out on an analytic Ital-Elettronica 'SP 21 F' mass spectrometer; we thank Prof. V. Caglioti for his advice and Mr. C. Luttazzi for his help.

## DEMONSTRATION OF AN AVIAN LEUCOSIS GROUP ANTIGEN BY IMMUNODIFFUSION

By LEONARD D. BERMAN\* and PADMAN S. SARMA†

U.S. Public Health Service, National Institutes of Health, National Institute of Allergy and Infectious Diseases, Laboratory of Infectious Diseases, Bethesda, Maryland

A COMPLEMENT-FIXING antibody response has been demonstrated in tumour-bearing mammals in the adenovirus<sup>1</sup>, polyoma<sup>2</sup>, SV40 (ref. 3) and Rous sarcoma<sup>4,5</sup> systems. This response has been shown to be directed against viral antigens in some cases, and in other cases against antigens present in tumours but not in standard viral preparations. In the case of the Rous system, the antigen in question was found in various tumour and viral preparations of all members of the

avian leucosis group, and was specific for that group of viruses<sup>4-7</sup>.

It was our purpose to determine whether the Schmidt-Ruppin (S-R) Rous hamster antibody not only fixes complement but also gives precipitation in agar gel. The basic technique consisted of testing various preparations of avian leucosis antigens against S-R tumour-bearing hamster serum with the Ouchterlony double diffusion technique.

The test used was a modification of the micro-method described by Crowle<sup>8</sup>. The agar was 1 per cent 'Ionagar' with 1 per cent sodium azide. Plates were routinely

‡ Normal chicken muscle, chorio-allantoic membrane and chick embryo fibroblast.

incubated for 48–72 h in a moist chamber, examined, dried, stained with a protein stain\* and examined again. Complement-fixation tests were carried out by the method previously described\*.

The following leucosis antigens were tested: Rous sarcoma (Bryan, Purdy and Schmidt-Ruppin strains), resistance-inducing factor (RIF) (a naturally infected chicken embryo fibroblast culture), lymphomatosis (organ extracts of a field case of visceral lymphomatosis), RPL 12 strain, myeloblastosis (strain A), erythroblastosis (strain R), and Warrenton agent (naturally occurring avian sarcoma)<sup>10</sup>. Fuginami and OT 10 avian sarcomata were also tested.

Antigen preparations included clarified extracts of chicken and hamster tumours, clarified chicken organ suspensions, chorioallantoic membrane preparations, infected chick fibroblast tissue, culture harvests\* and serum of viraemic birds. Most of these have been more fully described elsewhere\*. Hamster sera consisted of several lots of pooled Schmidt-Ruppin tumour-bearing hamster sera from animals with large transplanted tumours. Most tests were done with pool 11, which was derived from 15 hamsters and had a complement fixation titre of 1:160 against four units of hamster tumour extract antigen.

Results are summarized in Table 1. Both the Bryan and S-R strains of Rous sarcoma virus gave positive reactions. Both hamster and chicken tumours reacted with the latter strain. With the exception of Fuginami, OT 10, and RIF antigens, positive gel-diffusion reactions were obtained with at least one preparation of all the leucosis viruses tested. Although the Fuginami, OT 10 and RIF preparations gave positive complement-fixation reactions, the antigen may have been poorly precipitating.

A positive reaction usually consisted of a single precipitation line between the antigen in question and the hamster serum. Rarely this appeared as a double line. The occurrence of single or double reactions was not consistent in successive tests, and no definite pattern could be established. In all cases, however, the lines of the various antigens tested (whether single or double) were continuous, showing a reaction of identity. This was true regardless of the source of the preparation. No spurs or crosses were observed with the hamster serum. Fig. 1 is a pattern illustrating these findings. The hamster serum gives a continuous precipitation line with Bryan wing web tumour extract, myeloblastosis and lymphomatosis kidney extracts. The S-R hamster tumour extract at the top of the field did not react in this test. Two control antigens also failed to react.

Several attempts to use avian sera in the Ouchterlony system were unsuccessful. Despite the presence of high salt (8 per cent sodium chloride), the lines have either

been very faint or absent. The results of one pattern, however, did indicate at least partial identity, with spurring between the reactions of the avian hyperimmune and hamster sera. This indicated a possible one-way cross.

Immunoelectrophoresis (using Scheidegger's technique\*) was attempted in the hope of distinguishing any separate components in the system. Only one precipitation line, migrating toward the negative pole at pH 8.2, was found. However, the possibility that other components were lost cannot be excluded.

Attempts were made to determine whether the precipitating antigen was identical to the soluble complement-fixation antigen previously described\*. Gel-diffusion tests were performed on soluble and sedimentable fractions (pellet and supernatant of clarified tumour extract spun at 105,000g for 2 h) of S-R and Bryan chicken tumour extracts. Soluble and sedimentable fractions of a Bryan wing web tumour preparation having titres of 1:64 in complement fixation against S-R hamster serum pool 11 (refs. 4, 5) both gave positive reactions (Fig. 2). Similar results were also obtained with S-R wing web antigen. Precipitates were obtained with both ether-tested and non-treated material. In general, reactions with the sedimentable fractions tended to be somewhat more pronounced than those with the soluble fractions.

To show the specificity of the gel diffusion reaction, the S-R hamster serum was tested against many control antigens, all of which were negative. These included normal chick muscle, chorioallantoic membrane, and

Fig. 1. The S-R hamster serum undergoes a common reaction with the myeloblastosis, lymphomatosis and Bryan wing-web antigens. The S-R hamster antigen does not react in this test.

Fig. 2. Soluble and sedimentable fractions of Bryan wing-web tumour share a common reaction with the hamster serum.

Table 2. COMPLEMENT-FIXATION TITRES OF ROUS LEUCOSIS ANTIGENS IN RELATION TO REACTIVITY IN GEL DIFFUSION AGAINST S-R HAMSTER SERUM

Ouchterlony reaction	OF titres			Total
	High (64+)	Medium (16-32)	Low (0-8)	
Positive	18	9	1	28
Negative	5	11	16	32
Total	23	20	17	60

$$\chi^2 = 2.15, P < 0.05$$

chicken embryo tissue culture cells. Other chicken and human viruses which also failed to react included mumps, *ORLO* (ref. 11), vesicular stomatitis, a chicken enteric virus<sup>14</sup> and measles. Oncogenic viruses such as adenovirus 12 (virus and tumour extracts), *SV40* and Moloney mouse leukaemia virus were also negative when tested against the S-R hamster serum. In addition, tumour-bearing hamster sera of the adenovirus 12 and *SV40* systems and Yaba monkey tumour serum were all negative when tested against the S-R antigen (chorioallantoic membrane grown virus that reacted in gel with the S-R hamster serum pool 11).

Two other S-R hamster serum pools<sup>9,12</sup> and one individual hamster serum (24338) all gave identical reactions to that described here for hamster serum pool 11, with which most of the work was done.

Efforts were made to show statistical correlation between the complement fixation<sup>8</sup> and Ouchterlony results. These are summarized in Table 2, where all the antigens tested were arbitrarily divided into high (64+), medium (16-32) and low (0-8) reactors and compared with the Ouchterlony results. High complement-fixation titre and positive gel reactions correlate well, as evidenced by the  $P$  of  $< 0.01$  on  $\chi^2$  testing.

These results confirm the findings of Huebner *et al.*<sup>4</sup>, Sarma *et al.*<sup>5</sup>, and Armstrong *et al.*<sup>7</sup> regarding the presence

of a common group-specific antigen shared by all members of the avian leucosis group of viruses and reactive with the sera of hamsters bearing Schmidt-Ruppin tumours. The specificity of this gel-diffusion reaction for avian leucosis viruses has been confirmed by the negative control reactions with normal chicken antigens, unrelated avian viruses and non-avian tumour virus preparations. None of the tests provided unambiguous evidence for the presence of more than one antigen.

Gusev<sup>15</sup> has used the gel-diffusion test with hyper-immunized rabbit anti-Rous sera to demonstrate a specific Rous sarcoma antigen, not present in normal chick tissue or chemically induced tumours. It remains to be ascertained whether this antigen is the same as the one we have demonstrated.

We thank Dr. Wallace P. Rowe for his advice, and Dr. Robert J. Huebner and William T. Lane for providing tumour-bearing hamster antigens and antisera.

## PROLIXIN-S AND PROLIXIN-G; TWO ANTICOAGULANTS FROM *Rhodnius prolixus* STÅL

By DR. K. HELLMANN and DR. ROSEMARY I. HAWKINS

Chemotherapy Unit, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2

WE have previously described an anticoagulant<sup>1</sup> and a fibrinolysin<sup>2,3</sup> in the gut of the blood-sucking hemipteran *Rhodnius prolixus*, and another anticoagulant in the salivary glands of this insect. The two anticoagulant activities appeared to be due to two distinct substances, and experiments confirming this are described here. We have called these two activities prolixin-S and prolixin-G to indicate the anticoagulants from the salivary gland and gut respectively.

Saline extracts were prepared and tested as described earlier<sup>1</sup>. The salivary glands and the entire gut were dissected out and placed into ice-cold 0.9 per cent saline allowing 0.1 ml. for each insect. All extracts were homogenized and centrifuged and the supernatant, which contained the anticoagulant activity, was decanted and tested on recalcified horse plasma.

Neither extract could be diluted to any great extent without considerable loss of demonstrable activity. It seemed a possibility, however, that if their mechanisms of action could be established and if the crude extracts could be purified, more specific test systems and greater dilutions of the active materials might be used.

The actions of prolixin-G and -S were examined on isolated stages of the clotting system. The last stage, the conversion of fibrinogen to fibrin by thrombin, was examined first. If inhibition of this reaction was insufficient to account for the anticoagulant activity, the preceding stages of the clotting system were examined by

means of the one-stage prothrombin time<sup>4</sup> and the kaolin-cephalin clotting time<sup>5</sup>.

The action of thrombin (Leo Laboratories Ltd., 5 units/ml.) on bovine fibrinogen (0.5 per cent Armour Pharmaceutical Co. Ltd.) was inhibited by prolixin-G even at dilutions of 1 in 1,000. The antithrombin activity of prolixin-S was too weak, however, to account for its anticoagulant activity and it did not retard the one-stage prothrombin time. On the other hand, the kaolin-cephalin time was greatly prolonged, which suggested that prolixin-S inhibited any or all of the clotting factors VIII, IX, XI and XII. The increase in kaolin-cephalin clotting time was unchanged irrespective of whether prolixin-S was added before or after activation of the contact factors XI and XII. The implication, therefore, was that prolixin-S must interfere with the activation of factors VIII or IX. Reconstitution of factor VIII or IX deficient plasmas with their respective factors, which had previously been incubated with prolixin-S, showed that the main activity of this substance was on factor VIII (the anti-haemophilic factor).

Purification of prolixin-G was attempted by running extracts of gut in saline through 'Sephadex G 100' (1 g in saline; column width 1 cm; length 35 cm; fraction volume 2 ml.) and eluting with 0.9 per cent saline. When elution with distilled water was tried the activity precipitated out on the column. Antithrombin activity began to appear when the elution volume had reached 14 ml. and attained

its peak at 18 ml. The molecular weight of prolixin-*G* thus seemed to be greater than the exclusion limit (100,000 for 'Sephadex *G* 100'). When extracts were run through 'Sephadex *G* 200' (1 g in saline; column width 1 cm; length 35 cm; fraction vol. 2 ml.) the appearance of antithrombin activity was retarded and did not appear until fractions 42 and 43 (84–86 ml.). These results would seem to give prolixin-*G* a molecular weight of between 100,000 and 200,000. They also suggest that prolixin-*G* is a protein of high molecular weight and possibly a euglobulin; a suggestion supported by its solubility in saline and insolubility in distilled water.

Purification of the crude material from gut and salivary glands was also attempted by partial precipitation with alcohol, ammonium sulphate and acetone. Of these, acetone proved to be the most useful. Both prolixin-*G* and -*S* were precipitated by addition of 3 vol. of acetone to 1 vol. of extract, and prolixin-*G* could be extracted from the precipitate with 1 vol. of saline, but not with distilled water. On the other hand, with prolixin-*S* the reverse was the case. In both instances a large amount of inactive material remained in the precipitate.

Extraction of the acetone precipitate of gut extract with distilled water resulted in a clear solution, active in inhibiting the clotting of recalcified plasma though not the thrombin-fibrinogen reaction. This suggests that the activity recovered by distilled water extraction was not the gut antithrombin prolixin-*G*. If saline was used to extract the precipitate rather than distilled water, then the resultant activity had both a greater inhibition on the clotting of recalcified plasma, and an antithrombin activity. It is, therefore, reasonable to assume that the gut extract consists of the two activities prolixin-*G* and prolixin-*S*, though in greatly different proportions, and that prolixin-*S* is found in the gut extract because it is carried back with the blood meal.

Acetone precipitation of gut extract and saline extraction of the precipitate achieved an approximately ten-fold purification of prolixin-*G* when calculated on the nitrogen content of the crude and extracted material (Table 1).

Table 1. NITROGEN CONTENT OF EXTRACT BEFORE AND AFTER PURIFICATION

µg Nitrogen per ml. extract		
Estimation	Crude	Purified
I	8,100	800
II	1,060	137

The inhibition of thrombin by gut extract was found to be a time-consuming reaction. When gut extract and thrombin (5 units/ml.) were incubated together at 37° C and 0.1 ml. aliquots added to fibrinogen every minute, the length of the clotting time increased with length of incubation. After 10 min a maximum of approximately three times the original inhibition was reached and on further incubation the clotting time decreased again. When, however, partially purified prolixin-*G* was incubated with thrombin, the clotting time increased over a period of 1 h, at which time it was five times that of the initial value. It is probable, therefore, that in the crude extracts, gut enzymes destroy prolixin-*G*. Furthermore, it appears that the reaction between prolixin-*G* and thrombin is not stoichiometric.

It seemed possible that prolixin-*G* might be derived from prolixin-*S* by digestion in the gut of the insect. In order to test this possibility, gut extracts were incubated with prolixin-*S*. If the hypothesis was correct, then an increase of prolixin-*G* might be expected to develop in the incubation mixture, but no such increase occurred. It is unlikely, therefore, that although both substances are found in the gut any conversion of prolixin-*S* to prolixin-*G* occurs.

Tests using the thrombin-fibrinogen reaction confirmed earlier findings reported on plasma<sup>1</sup> that loss of activity was slight when gut extracts were heated to 80° C for 5 min, but considerable after 5 min at 100° C. The clotting inhibition of prolixin-*S* and prolixin-*G* remained largely unaffected at 4° C, but prolixin-*G* increased with

standing freezing and immediate thawing could not be stored at -20° C without loss of activity during the first 24 h, after which period no further loss occurred. This is somewhat difficult to explain, though the effect of freeze-drying the gut extract which always resulted in a moderate loss of activity is more readily understandable. In contrast to this, prolixin-*S* could be stored at -20° C, and freeze-dried, without loss of anticoagulant action.

Attempts to stabilize prolixin-*G* by adjusting the pH showed that alkalinization did not prevent the loss of activity which occurs on standing for 24 h or longer at room temperature while acidification to pH 3 did so in 3 out of 5 experiments.

Better results were obtained when the crude extract prepared in the usual way was dried at room temperature in a desiccator under reduced pressure and over calcium chloride. It would then store at 4° C without appreciable loss of anticoagulant activity.

Dialysis of salivary gland extract at 4° C against saline caused no appreciable loss of activity of prolixin-*S*, but gut extracts lost about half their prolixin-*G* activity.

Gut extract incubated for 10 and 30 min with a concentration of trypsin which failed to affect the test reactions (final concentration of 10<sup>-3</sup> mg/ml.) resulted in a slight reduction of anticoagulant activity on recalcified plasma, but did not affect the increase of clotting time of the thrombin-fibrinogen reaction. On the other hand, with salivary gland extracts, a considerable loss of activity occurred after incubation for 10 min.

It is clear from the foregoing experiments that the plasma test system is not sufficiently critical to distinguish between the anticoagulants prolixin-*S* and prolixin-*G* in gut extracts, and that only with a more specific test system, such as the thrombin-fibrinogen reaction, can these activities be separated. A summary demonstrating this point is given in Table 2.

A quantitative assay of the antithrombin activity of partially purified gut extract was made using the thrombin-fibrinogen reaction. 1 mg of this extract had an antithrombin activity of 100 antithrombin units (ATU), where 1 ATU is equivalent to that amount of heparin which blocked one National Institutes of Health Unit of thrombin. Heparin under the same experimental conditions has an activity of 500 ATU/mg and 1 mg of hirudin is reported to neutralize 8,500 units of thrombin<sup>4</sup>.

Because of the relative stability of the prolixin-*G* to acidification it seemed unlikely, however, that it was either a heparinoid substance or heparin itself<sup>4</sup>. This assumption was strengthened by lack of inhibition of prolixin-*G* by protamine sulphate and lack of meta-chromatic reaction with toluidine blue<sup>3</sup>. It would also suggest that prolixin-*G* is not a highly sulphated compound. Prolixin-*G* and heparin do, however, give similar dilution curves when tested on plasma (Figs. 1 and 2).

The differences in molecular weight (hirudin mol. wt. equals 18,000 (ref. 5); prolixin-*G* mol. wt. equals 100,000–200,000) rule out the possibility that the gut antithrombin activity of *Rhodnius prolixus* is due to hirudin.

No anticoagulant activity could be demonstrated in gut extracts prepared immediately after a blood meal (although this developed 4 h later (Fig. 3)). However, the

Fig. 3. Effect of starvation on prolixin-G (x) and prolixin-S (O) activity

salivary gland activity did not disappear after feeding and, therefore, gut extracts might have been expected to show some prolixin-S activity.

It seemed possible that anticoagulant action in these extracts was masked by inhibitors, an assumption which was the more likely when acetone precipitation or heating to 60° C for 3 min revealed anticoagulant activity (Table 3).

60° C for 3 min	19'

Markwardt and Schulz<sup>7</sup> have obtained an anticoagulant, reduviin, by puncturing the abdomen of *Rhodnius prolixus* fed on saline. This anticoagulant, which was claimed to be largely purified, was found to react stoichiometrically with thrombin, with an activity of 10 ATU/insect. This compares with 50 ATU/insect found with our partially purified material which does not appear to enter into a stoichiometric reaction with thrombin. Artificial diets such as saline are known to alter drastically enzyme activities in the insect gut<sup>8</sup>, and it is difficult to know whether in this particular instance secretions are stimulated when the insect is fed this artificial diet. Because the gut anticoagulant in the normally fed insect is a mixture of prolixin-S and prolixin-G, it is also difficult to compare these two anticoagulants with that described by these authors. It is furthermore conceivable that other members of the reduviid family may possess anticoagulants with different characteristics from those of *Rhodnius prolixus*<sup>9</sup>. For all these reasons and whatever may be the character of the anticoagulant described by Markwardt and Schulz, we regard the name reduviin as inappropriate.

In contrast to the 'anticoagulin' present in certain species of mosquitoes, prolixin-S and prolixin-G are found in both sexes of the adult insect and in the pre-adult nymph stages. Furthermore, no evidence has been obtained of the presence of any 'coagulin' or agglutinin such as have been reported for some mosquitoes<sup>10</sup> and blood-sucking muscids<sup>11</sup>.

Naturally occurring antithrombins are known in blood-suckers, but the presence of an antifactor VIII has not previously been reported, and the presence of two anticoagulants with different mechanisms of action in one such insect also appears not to have been previously recorded.

We thank Prof. R. G. Macfarlane and Dr. Rosemary Biggs for their advice and Mr. B. J. Ash (Medical Research Council Blood Coagulation Unit, Oxford) and Mr. D. Duke and staff for their assistance and Mr. G. R. N. Jones (Royal College of Surgeons) for the nitrogen determinations.

## EFFECT OF OXYGEN PRESSURE ON RADIOSENSITIVITY OF EHRLICH ASCITES TUMOURS AT VARIOUS INTERVALS AFTER INOCULATION

By H. A. S. van den BRENK and NANCY SPARROW

Radiobiological Research Unit, Cancer Institute Board, 278 William Street, Melbourne, Australia

THESE experiments were designed to compare the radiosensitivity of the hyperdiploid Ehrlich ascites tumour ELD Lettré (EAT) cell X-irradiated *in vitro* in the presence of either nitrogen at 1 atmosphere or oxygen at 5 atmospheres absolute pressure (HPO). The method was essentially that described by Dechener

and Gray<sup>1</sup>. The ascites tumour was removed after 5 days growth in O3H mice. The fluid from 3 or 4 mice was rapidly pooled and diluted to 4 ml. with normal saline solution at 35° C. This sample was introduced into a flat polystyrene dish, which was placed in a special pressure vessel consisting of an insulated water-jacketed steel

chamber, thermostatically controlled to  $\pm 0.5^\circ\text{C}$ , with a 'Perspex' irradiation portal sealed into the flat upper surface. The latter was removable and sealed by an O-ring pressure seal. The gas circulated through a metal coil in the water-jacket and entered the chamber through 3 angled microjets directed to the surface of the fluid as described by Gray<sup>2</sup>. The circular stirring action gave rapid equilibration. Using pure nitrogen ( $\text{O}_2$  content  $< 20$  p.p.m.) as the gas phase at atmospheric pressure at  $20^\circ\text{--}35^\circ\text{C}$ ,  $p\text{O}_2$  was measured with open-ended gold electrodes<sup>3</sup> and showed zero current in the fluid within 5 min of commencing gassing. 20–25 min equilibration time preceded all irradiations. The plastic dish rested on bolus material in the chamber and was surrounded by similar bolus to provide back scatter. The X-ray factors used were 200 kV, 15 mA half-value layer 1.0 mm Cu, giving a dose rate in the fluid of 52.8 rads/min. The dose variation, measured within the 2-mm depth of ascitic suspension, was  $\pm 3$  per cent. The time taken between aspiration of the donor cells and re-inoculation of recipient mice with 0.3-ml. aliquots of the suspension after irradiation or mock irradiation was less than  $1\frac{1}{2}$  h. 20–25 min was allowed for gas equilibration and 10–20 min for radiation times. For a further 20–25 min, the same gas phase was maintained as a post-irradiation treatment. Thus about 30 min was largely occupied in preparing the suspension, etc., before gassing and re-inoculation of mice. At intervals of 6–24 h after inoculation, recipient mice were killed by cervical fracture and peritoneal fluid was removed and added to acetic-methanol (1:3) for fixation. Smears were prepared and stained in acetic-orcein, and all telophase abnormalities (acentrics and dicentrics), classed as bridges, fragments or both, were scored and pooled as aberrations. 100 (including normal) telophases were scored per slide. Percentage aberrations for 4–6 slides per mouse were averaged. The statistical analysis was based on 8–48 mice per post-inoculation time. Doses used were 20–250 rads in HPO, and 40–875 rads in  $\text{N}_2$ . However, samples irradiated with lower doses and showing  $< 10$  per cent aberrations after correction for the spontaneous aberration rate, which averaged 4 per cent for parallel gassed but unirradiated controls, were excluded to restrict calculation of aberration coefficients to the exponential portion of the dose-response curves (see below). The aberration coefficients ( $\alpha$ ) were calculated as described by Gray<sup>2</sup> from:

$$\alpha = \frac{\log_e F_i - \log_e F_R}{D}$$

where  $F_R$  and  $F_i$  represent the percentage abnormal telophases in irradiated and unirradiated control samples respectively and  $D$  is the dose in rads.

In our irradiated material, a peak in the induction of abnormal telophases at 15 h post-inoculation time, described by Deschner and Gray<sup>1</sup> for both  $\text{O}_2$  and  $\text{N}_2$  irradiations, did not occur. In similar studies of Hornsey *et al.*<sup>4</sup>, radiosensitivity parameters were calculated 18 h after inoculation, but their reported data did not establish a significant maximum effect for this time. Gray *et al.* have recently reported a "shift" in the peak effect for "aged" cells to a shorter post-inoculation time<sup>5</sup>. In our material, percentage aberrations for all radiation doses in HPO,  $\text{O}_2$  and  $\text{N}_2$ , respectively were consistently higher at shorter post-inoculation times (6–8 h), and thereafter progressively decreased (Fig. 1). However, aberration rates were high and mitotic indices low for early post-inoculation times (6–10 h) for HPO,  $\text{O}_2$  and  $\text{N}_2$  exposures respectively.

A striking difference between irradiations in HPO and  $\text{N}_2$  was that the mitotic index at 6 h in HPO was too low to score the incidence of aberrations. This applied also to the unirradiated HPO control samples. However, the spontaneous aberration rates in unirradiated HPO-exposed cells were not significantly greater than those in  $\text{N}_2$  controls irrespective of post-inoculation time and never

exceeded 5 per cent. Apparently HPO *per se* induced a period of arrest in cell division. Oxygen at 1 atmosphere caused less mitotic delay. The arrest in HPO could not reasonably be attributed to the medium (normal saline) used to suspend cells, to temperature differences ( $35^\circ\text{C}$  throughout) or to 'ageing' or 'metabolic damage' resulting from different pre- or post-irradiation manipulation times. The latter were kept to a minimum despite the report<sup>1</sup> that when cells stood for 30 min after irradiation at room temperature the results were not significantly affected and, in experiments lasting 6–8 h, spontaneous aberration rates did not increase.

The results illustrated by Fig. 1 showed that aberration rates for several post-inoculation times should be measured to study the oxygen effect. However, a further complication arose in the calculation of aberration coefficients. Log response-dose curves for irradiations in HPO and  $\text{N}_2$  were not strictly linear for higher doses in HPO which yielded  $< 40$  per cent normal telophases; the percentage telophase aberrations exceeded the value based on linearity, particularly for longer (16–24 h) post-inoculation

Fig. 1. Telophase aberrations induced in BMT cells by X-irradiation *in vitro* for various post-inoculation times in recipient mice

Fig. 2. Relation of radiation-induced aberration coefficients ( $\alpha$ ) to post-inoculation time. Interrupted lines represent regression for HPO and  $\text{N}_2$  radiations, respectively, calculated from data. Dotted line  $H$  represents the mean oxygen effect ratio based on linear regressions, and the lower (●) curve the values for  $H$  based on the experimental data. (○) represents  $\alpha$  for HPO, and (●)  $\alpha$  for  $\text{N}_2$  radiations, respectively

times. Moreover, responses for radiation doses in the range 40–875 rads in  $N_2$  and for post-inoculation times 6–24 h did not depart significantly from linearity.

Values of  $\alpha_{HPO}$  and  $\alpha_{N_2}$  for different post-inoculation times ( $T$ ) are plotted in Fig. 2, for radiation doses in HPO and  $N_2$  respectively, yielding 10–50 per cent aberrations at an exponential rate with increasing dose. The results show that the value of  $\alpha$  for both HPO and  $N_2$  varies with  $T$ . The data were fitted with regression lines, using the least-squares method on the assumption that  $\alpha$  decreased linearly with  $T$ . The regression equations:

$$\alpha_{HPO} = 4.08 - 0.058 T$$

$$\alpha_{N_2} = 1.03 - 0.008 T$$

were obtained and suggest that the oxygen effect factor  $E$

( $E_{HPO} = \frac{\alpha_{HPO}}{\alpha_{N_2}}$ ) decreases linearly from  $\sim 3.7$  ( $T=8$  h)

to  $\sim 3.2$  ( $T=24$  h). This result agrees with the value ( $E_{HPO} = 3.2$ ) obtained in this laboratory<sup>8</sup> for regression of this tumour growing in the leg of mice and irradiated *in vivo* in HPO or with tourniquet occlusion. However, a statistical analysis of the present data showed that the relation of  $\alpha$  to  $T$  was not linear. A variance ratio ( $F$ ) test gave a probability of  $P < 0.001$  that both regressions were non-linear. It appears that the relations of  $\alpha_{N_2}$  and  $\alpha_{HPO}$  to  $T$ , respectively, are curvilinear and that each regression may be better fitted by a polynomial cubic equation or a more complex regression of the general form:

$$\alpha = \beta + \beta_1 T + \alpha_2 T^2 + \beta_3 T^3$$

The data show that  $\alpha$  rises to a peak value ( $\alpha_p$ ) at time  $T_p$ , and afterwards rapidly decreased for a period of several hours. In Table 1 mean values of  $\alpha$  and the corresponding values of  $T$  are tabulated, and the values of  $E_{HPO}$  calculated.

Table 1

	6	8	10	14	16	18	24
$\alpha_{HPO}$	—	4.25	4.55	4.19	3.94	3.57	1.90
$\alpha_{N_2}$	0.95	1.40	1.00	0.91	0.72	0.75	0.84
$E_{HPO} = \frac{\alpha_{HPO}}{\alpha_{N_2}}$	—	3.03	4.55	4.60	4.08	3.43	2.26

Table 1 shows that calculated oxygen effect ratios vary considerably with post-inoculation time. The mean peak aberration coefficient ( $\alpha_p$ ) values give a ratio  $E_p$ —

$$E_p(HPO) = \frac{\alpha_p(HPO)}{\alpha_p(N_2)} = \frac{4.6}{1.4} = 3.3$$

This 2 h delay in  $T_p(HPO)$  ( $\approx 11$  h) after  $T_p(N_2)$  ( $\approx 9$  h) seems related to the delay in onset of mitosis due to HPO treatment *per se*. Assuming that ascites cells aspirated on the fifth day are in asynchronous logarithmic growth, parasynchrony possibly results from a temporary arrest in one or more selected phases of the cell replication cycle as a result of metabolic stresses produced by experimental manipulations. Evidence, somewhat conflicting, exists that cellular radiosensitivity may be decreased in the presynthetic ( $G_1$ ) 'resting' phase, but is greater in certain parts of other ( $S$ ,  $G_2$ ,  $M$ ) phases<sup>9</sup>. However, in certain hypotetraploid sublines of EAT, cell cycle times of about 18–20 h have been reported, the  $S$ -phase lasting 11–12 h and the post-synthetic ( $G_2$ ) period plus mitosis ( $M$ ) period 6–7 h, whereas  $G_1$  is very short or absent<sup>8</sup>. Thus, in 3–5 day EAT 54 per cent of interphase nuclei were labelled 1 h after <sup>3</sup>H-thymidine administration, and the mitotic index (including early prophase) was about 25 per cent<sup>8</sup>. In our hyperdiploid EAT, the corresponding 5-day cell cycle time was about 21 h,  $17 \pm 2.4$  per cent of interphase nuclei were labelled at 1 h and there were 4 per cent mitoses. This suggests that the  $S$  period is much shorter in the hyperdiploid tumour. Data based on labelling and mitotic indices after colchicine arrest indicated that the  $S$  plus  $G_2$  period is 6–7 h, and that

mitosis lasts about 1 h. A long prophase period (4 h) is reported for the hypotetraploid tumour<sup>8</sup>, but is much shorter in the hyperdiploid tumour. These differences in the growth cycles of hyperdiploid and hypotetraploid sublines appear important in evaluating radiosensitivity parameters.

Assuming  $\alpha_p$  to correspond to radiosensitivity being maximum in  $S$  phase, the values  $T_p(N_2) \approx 9$  h and  $T_p(HPO) \approx 11$  h seem to fit this hypothesis, since HPO caused more prolonged arrest of cells in all stages of division. Arrest of growth and division by HPO have been described in various biological systems<sup>9</sup>. Possibly HPO causes changes in endogenous SH — SS redox systems. The latter have been associated with various biosynthetic events in cell replication<sup>10</sup>, and shown to alter in HPO poisoning<sup>11</sup>.

Assuming  $\alpha_p$  values in our material to correspond to higher radiosensitivity of those cells in DNA synthesis at the time of irradiation, a calculation has been made of this increase in radiosensitivity ( $\theta$ ) for HPO and  $N_2$ , respectively (Table 2).

Table 2

Radiosensitivity ratio ( $\theta$ ) for peak value ( $\alpha_p$ ) relative to mean value ( $\alpha_m$ ) calculated from linear regression curve	$\theta_{HPO} \left( \frac{\alpha_p}{\alpha_m} \right)$	$= \frac{4.60}{3.45}$	$= 1.30$
	$\theta_{N_2} \left( \frac{\alpha_p}{\alpha_m} \right)$	$= \frac{1.40}{0.95}$	$= 1.45$
Extreme radiosensitivity ratio ( $\theta^1$ ) for peak value ( $\alpha_p$ ) relative to minimum value ( $\alpha_{min}$ ) at 24 h	$\theta^1_{HPO} \left( \frac{\alpha_p}{\alpha_{min}} \right)$	$= \frac{4.60}{1.90}$	$= 2.40$
	$\theta^1_{N_2} \left( \frac{\alpha_p}{\alpha_{min}} \right)$	$= \frac{1.40}{0.84}$	$= 1.67$

If  $\alpha_{max}$  in HPO and  $N_2$ , respectively, corresponds to cells irradiated in  $G_1$  phase, and seen in telophase at 24 h, the oxygen effect factor for  $S$  phase (for HPO) may be

$$\text{higher (by an additional factor } E_s = \frac{\theta^1_{HPO}}{\theta^1_{N_2}} = \frac{2.40}{1.67} \approx 1.4)$$

than for  $G_1$  phase. At present DNA labelling techniques in conjunction with measurement of aberration rates to identify phases of cell replication for HPO and  $N_2$  irradiations, respectively, are being used to verify this hypothesis.

In conclusion, the results obtained show that the incidence of chromosome aberrations in the hyperdiploid Ehrlich ascites tumour, induced by ionizing radiation *in vitro* and measured after incubation of the cells in recipient mice for varying times, is highly dependent on the post-inoculation period ( $T$ ). In both HPO (5 atmospheres absolute) and in  $N_2$ , respectively, the aberration coefficient ( $\alpha$ ) rises to a peak value ( $\alpha_p$ ) and then rapidly decreases as a curvilinear effect ( $\alpha = f(T)$ ). HPO treatments delay division by an additional  $\sim 2$  h and this effect corresponds to the HPO regression curve and  $\alpha_p(HPO)$  value being displaced to the right. Calculation of the oxygen effect factor ( $E$ ) must be based on a range of values of post-inoculation time ( $T$ ). Peak  $\alpha$  values observed are considered to represent a higher radiosensitivity of cells in DNA synthesis (or possibly  $G_2$ ) at the time of irradiation. The mean oxygen effect factor  $E_{HPO}$  ranged from 3.7 to 3.2 for  $T = 8$  to  $T = 24$  h, respectively. The value  $E_p = 3.3$  (for corresponding peak values of  $\alpha$ ) was similar. However, values of  $E_{HPO}$  corresponding to the various values of  $T$  after radiation in HPO and  $N_2$ , respectively, ranged from as high as 4.60 to as low as 2.26—an anomaly partly due to an additional mitotic delay caused by HPO, but also attributed to a higher oxygen effect factor for cells irradiated during DNA synthesis ( $S$  phase). An estimate of the ratio ( $E_s$ ) of oxygen effect factors for cells in DNA synthesis to that for  $G_1$  cells is 1.4. The oxygen effect factor for X-irradiation in HPO was  $\sim 2.3$  minimum for cells considered to be mostly in the presynthetic  $G_1$  phase, and  $\sim 3.3$  for cells in DNA synthesis ( $S$  phase). The practice adopted of calculating oxygen effect ratios from peak aberration rates, irrespective of post-irradiation incubation time, seems unacceptable if radiosensitivity varies during the replication cycle, and if experimental factors produce selective effects on

timing of the replication cycle or differential sensitizing, protective or additive effects related to phases of replication.

## SILURIAN MARINE COMMUNITIES AND THEIR ENVIRONMENTAL SIGNIFICANCE

By A. M. ZIEGLER

Division of the Geological Sciences, California Institute of Technology, Pasadena, California

PETERSEN<sup>1</sup>, in a classic investigation in marine ecology, demonstrated that the benthonic animals of Danish waters tend to occur in several distinctive communities, and he produced maps showing the distribution of these communities. Other workers<sup>2,3</sup> have followed Petersen's lead in treating the animal community as the basic ecological unit, and the general implication is that communities are ultimately controlled by environmental factors. If this is true, then maps showing the distribution of co-existing communities in remote geological times should reflect the different environments of those times; furthermore, the relationships of the communities to such geologically verifiable features as shorelines should provide a clue to the type of environmental factors responsible. Although some palaeontologists<sup>4,5</sup> have defined specific fossil communities in Palaeozoic rocks, few have been able to map coexisting communities, probably because of the difficulties of stratigraphical control.

The early Silurian deposits of Wales and the Welsh Borderland contain fossil assemblages which fall naturally into several groups. The distinctions between some of the assemblages were noticed by earlier workers who invoked proximity to volcanoes<sup>6</sup> or submarine ridges<sup>7</sup> to account for the differences. At least five assemblages or communities may now be recognized, and these are briefly defined in Table 1. In the column headed 'Characteristic Species' are the animals which normally occur abundantly in the community; the 'Associated Species' usually occur in the community, but are not as abundant or regular in their appearance. The communities are probably completely intergrading, and it should be emphasized that their recognition depends as much on relative abundances of species as it does on occurrences of particular species; thus *Ecocelia* is very abundant in its own community, but it frequently occurs in the *Pentamerus* community and is found occasionally in the other communities. The communities are widely distributed and, in fact, the same associations occur in collections known to me from as far afield as Alabama and Hudson's Bay.

The five communities: (1) *Lingula*; (2) *Ecocelia*; (3) *Pentamerus*; (4) *Stricklandia*; (5) *Olorinda*, are related to each other in a linear fashion; adjacent communities, for example 1 and 2, or 4 and 5, have many species in common, while 1 and 4, or 2 and 5, are mutually exclusive. The communities defined, with the exception of the

Table 1		
Community name	Characteristic species	Associated species
1. <i>Lingula</i> community	<i>Lingula pseudoparallela</i> <i>Cameroecocelia decemphloia</i> <i>Nucula eschscheri</i>	<i>Hormotoma</i> sp. <i>Pterinea</i> sp. <i>Cornulites</i> sp.
2. <i>Ecocelia</i> community	<i>Ecocelia</i> spp.* <i>Leptocryptus</i> sp. <i>compositus</i> <i>Delavensis eschscheri</i>	<i>Hemellia crispata</i> <i>Salopina</i> sp. <i>Pterinea</i> sp.
3. <i>Pentamerus</i> community ( <i>Pentameroides</i> community)*	<i>Pentamerus</i> spp.* <i>Atrypa reticularis</i> <i>Dalmanella</i> sp.	<i>Ecocelia</i> spp.* <i>Hemellia crispata</i>
4. <i>Stricklandia</i> community ( <i>Coelotrichianella</i> community)*	<i>Stricklandia</i> spp.* <i>Ecypirifer radiatus</i> <i>Atrypa reticularis</i>	<i>Renssela</i> sp.
5. <i>Olorinda</i> community	<i>Olorinda</i> spp.* <i>Dicelotris blobs</i> <i>Cyrtus asperatus</i> <i>Stenidiolites laevi</i>	<i>Plectodonta willmerensis</i> <i>Oolonia applanata</i> <i>Plectrotrypa marginata</i>

\* Chronological species or genera succeed one another in the same community.

*Lingula* community, are dominated by articulate brachiopods which typically constitute more than 85 per cent of the fossil remains, so the distinctions between the communities are based largely on the brachiopods. In the case of the *Lingula* community, only one species of

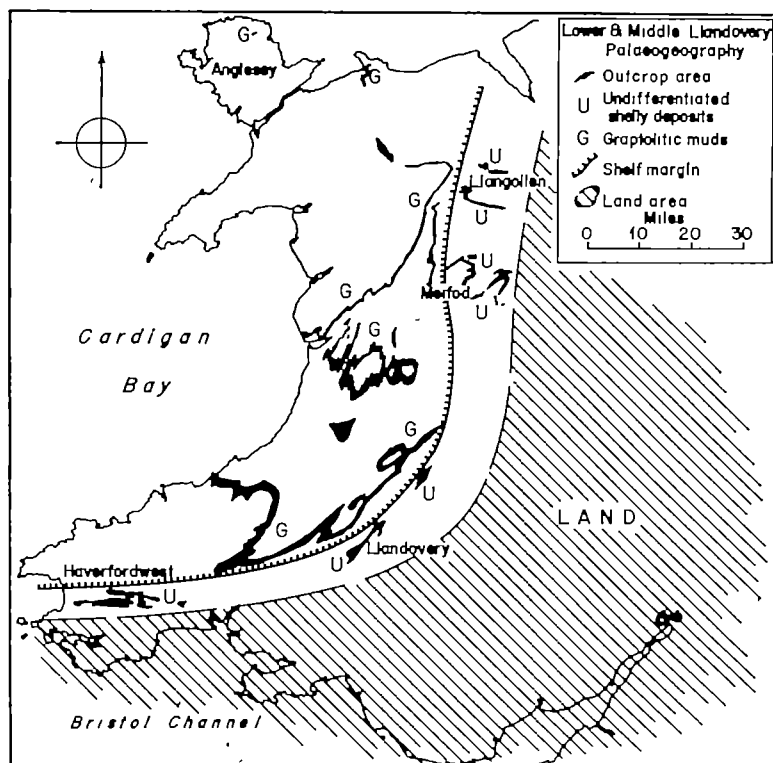

Fig. 1

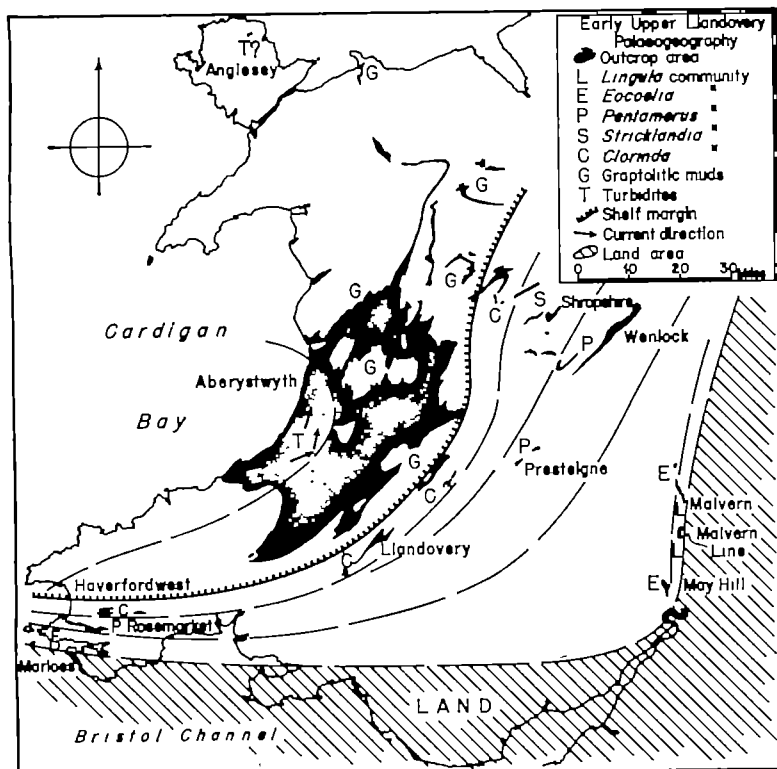

Fig. 2

articulate brachiopod, a rhynchonellid, is present, and many groups such as the corals, crinoids, and trilobites are completely unrepresented. Because of the restricted nature of this community and because of its occurrence at the base of transgressive sequences, such as the Kenley Grit of Shropshire, or the Cowleigh Park Beds of the Malvern Hills, a coastal environment is postulated, similar perhaps to the environment inhabited by many modern lingulids<sup>4</sup>.

Sediment type does not seem to have been a controlling factor in community distribution, as each community has been found in a wide range of sedimentary rocks. But there is a general tendency for communities 1 and 2 to occur in sandstones, communities 3 and 4 in sequences of varying proportions of sandstone and shale beds, and community 5 in shale.

It is evident that a transgressing sea, such as the Upper Llandovery sea of the Welsh Borderland, would deposit stratigraphical sequences representing environments progressively farther from the shore. The Damery Beds of Tortworth show the stratigraphic sequence of communities 2, 3, and 4, whereas at May Hill the community sequence is 2 (Huntley Hill Beds), 3, 4 and 5 (Yartleton Beds). In the Malvern District the community sequence is at Eastnor 1 (Cowleigh Park Beds), 3, and 4 (Wyche Beds); at Gulley quarry it is 3 and 4 (Wyche Beds); and at Old Storridge Common it is 2 (Cowleigh Park Beds), 3, 4, and 5 (Wyche Beds). In Shropshire the general sequence is 1, 3 and 5, representing the Kenley Grit, *Pentamerus* Beds and Purple Shales respectively. Thus the communities, as numbered, represent progressively offshore environments, though the complete sequence of communities is not present in any one area.

The off-shore sequence of the communities may be clearly demonstrated with palaeogeographical maps showing two phases of the Upper Llandovery transgression (Figs. 2 and 3). The communities of the Lower and Middle Llandovery have not yet been studied in detail, but a map of this time period has been included (Fig. 1) to show the extent of the land area later flooded by the Upper Llandovery transgression, and also to contrast the widths of the shelf area during different times. The accuracy of these maps depends largely on the correlation of the various sections, and this has been accomplished by studying evolutionary trends in various brachiopod lineages<sup>5</sup>. The graywackes and the graptolitic muds are included on the maps; these deposits typically do not contain benthonic animals. The graptolites are largely restricted to these deposits, only because the environment of deposition was such that their delicate remains were preserved; they probably lived in the surface waters<sup>10</sup> and drifted wherever seas existed.

A first approximation of the depths at which the various communities existed may be derived from volcanic flows which occur both at Marloes, Pembrokeshire, and Tortworth, Gloucestershire<sup>11</sup>. At Renny Slip, near Marloes, a 20-ft. thick pillow basalt flowed out on deposits containing an *Eocoelia* community. The water was apparently shallowed by an amount equal to the thickness of the flow and this was enough to displace the *Eocoelia* community by its neighbour, the *Lingula* community which occurs in the beds just above the flow. However, the duration of the *Lingula* community at this locality was short as the *Eocoelia* community occurs about 40 ft. higher in the succession, its return being due to the

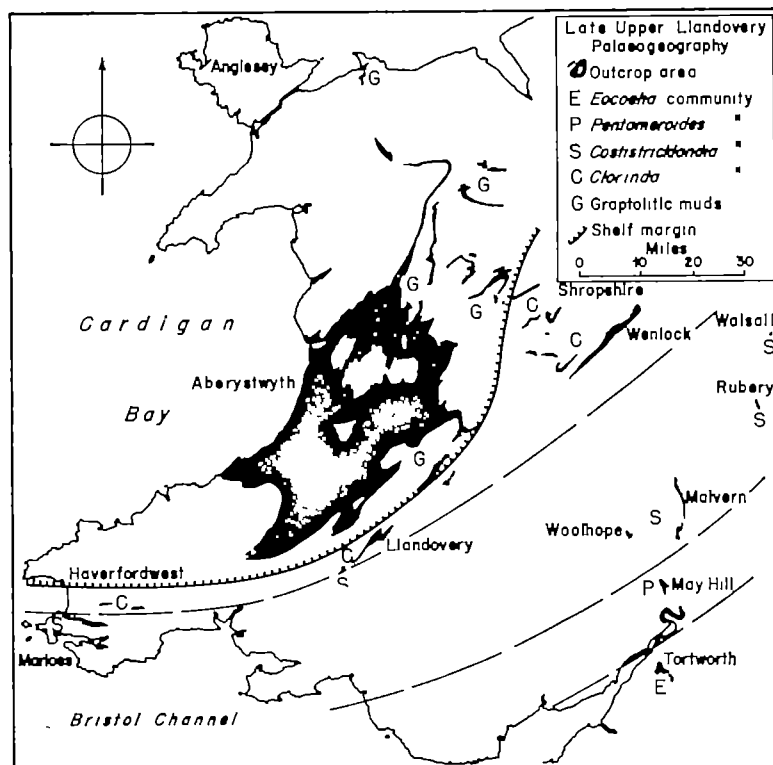

Fig. 3

generally transgressive nature of the sea at this time. Two miles away, however, at Marloes Bay, the basalt is much thicker (130 ft.) and therefore had a greater effect. Two flows occurred and the lower flow has a red-dened surface<sup>11</sup>, suggesting that deposition of the lower flow was at least in part subaerial. The *Lingula* community did not return until several hundred feet of conglomerates and sandstones had been deposited on top of the basalts. The relationships of these volcanic flows suggest that the depth ranges of these communities were of the order of tens of feet rather than hundreds of feet.

In the Tortworth inlier, an andesite flow of variable thickness occurs on top of deposits containing the *Costistricklandia* community. At Woodford, its thickness is small, perhaps 15 ft., and the *Costistricklandia* community is developed on top of the flow. However, less than two miles to the south, the flow is 150 ft. thick and the *Ecocelia* community is developed in the sediments above the flow; here, both the *Costistricklandia* and *Pentameroides* communities were displaced. Relief of 135 ft., then, seems likely between the levels of the *Ecocelia* and *Costistricklandia* communities, and the *Pentameroides* community must have occupied some intermediate range.

In summary, the various lines of evidence on the community environments are: (1) comparison with modern communities in the case of *Lingula*; (2) sediment type; (3) stratigraphical succession; (4) areal relationships; (5) volcanic displacement. All these considerations point to an off-shore sequence of the communities, the *Lingula* community being the closest to the strand and the *Clorinda* community furthest from the strand. If this interpretation is correct, then several conclusions regarding the geological history follow.

The transgression of the Upper Llandovery sea occurred in two pulses. In early Upper Llandovery times the sea extended to cover much of South Wales and most of the Welsh Borderland. The record of its relatively rapid transgression is preserved in the *Ecocelia* community low in the succession of Presteigne and the *Lingula* community of the Kenley Grits of Shropshire. This was just a transient phase, however, and Fig. 2 shows the relationships during much of early Upper Llandovery time, with the shoreline existing at the 'Malvern Line'<sup>12</sup>. About this time, turbidity currents began to deposit the Aberystwyth Grits in the geosyncline<sup>14</sup>. These turbidites are known to have extended further to the east and north with time, eventually covering much of central Wales<sup>15</sup>. It is a singular fact that there is a gap in the sequences of the shelf area which corresponds quite well with the deposition

of the turbidities in the geosyncline; for example, north-west of Malvern at Old Storridge Common, Wyche Beds of *O*<sub>1</sub> age rest directly on Cowleigh Park Beds of *O*<sub>1</sub> or *O*<sub>2</sub> age. Possibly there was a slight regression causing much of the sediment that had accumulated on the shelf to be transported to the shelf margin where it was carried to the depths of the geosyncline by turbidity currents. Confirmation of this regression is found at Llandovery, about the only place where the sequence is continuous, where the *Stricklandia* community of *O*<sub>4</sub> beds succeeds the *Clorinda* community of *O*<sub>1</sub>-*O*<sub>3</sub> beds.

The second pulse of the transgression occurred about *O*<sub>5</sub> time. It is perhaps significant that a transgression occurred on the north side of the geosyncline as well, in County Galway, Ireland<sup>16</sup>, suggesting that the change of sea-level was eustatic. Much of south-east England became submerged, to judge by bore-hole information<sup>17</sup>, turbidite deposition stopped abruptly, and fine-grained shales accumulated over much of the shelf and deeper area. By the end of Upper Llandovery times, the *Clorinda* community existed as far east as May Hill and Old Storridge Common, showing that subsidence continued at a faster pace than the accumulation of sediment.

To conclude, it is clear that the animal community technique of the ecologists is applicable to fossil assemblages and can provide the basis for interpreting past environments. This article reports some preliminary results and is intended only as an announcement of a much more complete treatise, which would define the communities quantitatively, describe the various stratigraphical successions, and present a detailed geological history of the Llandovery of the British Isles.

## PARTICIPATION OF ADRENOCORTICAL HYPERACTIVITY IN THE SUPPRESSIVE EFFECT OF SYSTEMIC ACTINOMYCIN D ON UTERINE STIMULATION BY OESTROGEN

By BARBARA M. LIPPE\* and PROF. CLARA M. SZEGO

Department of Zoology, University of California, Los Angeles

INVESTIGATIONS in several laboratories have been directed toward localization of the oestrogen-sensitive step(s)<sup>1-3</sup> in uterine metabolism. In a recent series of reports<sup>4-7</sup> reviewed elsewhere<sup>8</sup>, evidence has been provided that augmentation of RNA synthesis is an early correlate of oestrogen action in the uterus. Thus, actinomycin D, which inhibits DNA-dependent RNA synthesis in isolated systems<sup>9,10</sup> and depresses *in vivo* the incorporation of labelled orthophosphate into all forms of RNA in rat liver<sup>11</sup>, also inhibits some characteristic early actions of oestrogen on the rat uterus including imbibition of water

and accentuation of phospholipid and protein synthesis<sup>4,12</sup>. Moreover, augmentation of uterine RNA polymerase activity has been noted within 2 h of oestrogen pretreatment<sup>4,13</sup>. Puromycin administration abolished this response<sup>4</sup>, as well as the anabolic effects of the hormone<sup>4,14</sup>.

Enhancement of RNA synthesis is undoubtedly an early indicator of the uterine stimulatory action of oestrogen. This would be anticipated from the generalized accentuation by oestrogen of anabolic responses including that of protein elaboration<sup>1</sup>. What is less clear, however, is whether the hormone influences RNA synthesis directly as a primary step on which the metabolic stimulatory pattern depends<sup>4,15,16,17</sup>, or whether the accentuated rate

\* Supported by medical student research training grant 575 GM 43-03, U. S. Public Health Service, 1-50-1 PR 06355-01.

of formation of RNA is but one of the secondary consequences of increased availability of substrates, co-factors and energy sources resulting from oestrogenic stimulation of localized transport<sup>8</sup>.

The work recorded here demonstrates that a significant portion of the inhibitory influence of actinomycin pretreatment on oestrogen stimulation of uterine metabolism is due to activation of adrenocortical hypersecretion by this highly toxic<sup>17</sup> antibiotic. This inhibitory effect can be prevented or partially overcome by prior adrenalectomy or by swamping doses of oestrogen. The counteractive influence on oestrogen action of adequate concentrations of exogenous 0-11 steroids<sup>1</sup> and of endogenous adrenocortical hypersecretion<sup>18</sup> has long been known.

Female Sprague-Dawley rats, 2 months old and weighing about 200 g were used. They were ovariectomized 14-16 days earlier. Adrenalectomy, where indicated, was performed 24 h prior to experiment. Post-operatively, adrenalectomized animals were given 0.9 per cent saline as the drinking fluid. Actinomycin D, 375 or 500 µg in 0.5 ml. of 0.154 M neutral sodium chloride containing 1 per cent ethanol, or the saline control solution, was injected intraperitoneally 30 min before oestrogen treatment. Oestradiol-17β (1 µg in 1 ml. of saline)<sup>1</sup>, or the appropriate control solution, was administered via the saphenous vein under light ether anaesthesia. Four hours later the animals were bled under light sodium pentobarbital ('Nembutal') anaesthesia. Uterine horns were incubated at 37.5°-38° C in Krebs-Ringer-bicarbonate buffer under a constant stream of 95 per cent oxygen-5 per cent carbon dioxide in the presence of radioactive substrates for 2 h (ref. 8). Substrates added to 2 ml. medium were either 0.133 µmole glycine-U-<sup>14</sup>C (Nuclear-Chicago) or 0.175 µmole adenine-8-<sup>14</sup>C (Schwarz), in 0.1 or 0.25 ml. water, respectively. After incubation, the contents of each beaker were rapidly brought to 5 per cent trichloroacetic acid (TCA) and frozen at once. Protein isolation, plating and gas-flow counting procedures were essentially as earlier described<sup>8</sup>. The final weight of the plated radioactive protein plus carrier was 30 mg. Isolation of nucleic acids and separation into RNA and DNA fractions were carried out by methods similar to those described by Wool<sup>19</sup>. RNA and DNA concentrations were determined by ultra-violet analysis, and by the orcinol and the diphenylamine reactions, respectively. Radioactivity in aliquots of uterine nucleic acid fractions was measured by liquid scintillation counting in the Bray<sup>20</sup> medium.

**Uterine water.** Fig. 1 reveals that the characteristic water imbibition response to 1 µg oestradiol-17β was abolished ( $P < 0.01$ ) by actinomycin D pretreatment (375 µg). In contrast, the effectiveness of the hormone was not diminished by actinomycin D if prior adrenalectomy had been carried out. Adrenalectomy alone had no influence ( $P > 0.06$ ) on oestrogen sensitivity 24 h following operation. Suppression of the effects of swamping doses of oestradiol required proportionately higher concentrations of actinomycin D. Thus, in the presence of 10 µg of oestradiol, little or no curtailment of the uterine water response was noted ( $83.91 \pm 0.26$  per cent versus  $83.11 \pm 0.22$  per cent), unless the antibiotic was increased to 750 µg. Moreover, when experiments were carried out with animals which had been ovariectomized only 7 days earlier and therefore were unusually sensitive to oestradiol, incomplete obliteration of the uterine response was achieved with 375 µg actinomycin D (data not shown). These observations appear to render untenable the hypothesis<sup>2-5,12,14,15</sup> that even the uterine permeability changes elicited by oestrogen require prior induction of specific proteins.

**Protein labelling *in vitro*.** Uterine segments taken from animals pretreated as described above were tested for their capacity to incorporate radioactivity from glycine-U-<sup>14</sup>C into protein *in vitro*. The increased specific activity of uterine protein due to oestrogen administration was

Fig. 1. Suppressive influence of actinomycin D pretreatment on oestrogen-stimulated uterine water imbibition and its reversal by prior adrenalectomy. The height of the bars represents the average uterine water content<sup>1</sup> of groups of 4-8 ovariectomized rats treated as indicated. The positive segments of the S.E.M. are shown.

Fig. 2. Incorporation of radioactivity from glycine-U-<sup>14</sup>C into protein of surviving uterine segments: reversal by prior adrenalectomy of the suppressive influence of actinomycin D on oestrogen stimulation. The data (corrected for background and self-absorption as previously described<sup>8</sup>) indicate the results of successive experiments carried out at 2 levels of administered antibiotic. Each bar represents the mean of 3-4 observations, except for the last bar which represents 2 cases.

reduced to the control level by actinomycin D (Fig. 2). Prior adrenalectomy, however, restored a substantial portion of the hormonal sensitivity.

**Plasma corticosteroid levels.** Direct evidence for stimulation of adrenal cortical secretion by actinomycin D in ovariectomized, otherwise intact animals was seen (Fig. 3) in the sharply elevated levels of circulating corticosterone ( $P = 0.02$ ) with both doses of the antimetabolite (see also ref. 21). Levels of plasma corticosterone in adrenalectomized animals receiving actinomycin D were minimal as anticipated.

These dramatic effects of actinomycin D on circulating steroids were associated with intense adrenocortical hyperactivity as judged by extreme lipid depletion of all but the immediately subcapsular zone of representative frozen sections. A similar situation may occur with puromycin<sup>22</sup> and cycloheximide<sup>23</sup>, highly toxic inhibitors both of protein synthesis<sup>24</sup> and of uterine responsiveness to oestrogen<sup>2,24</sup>. Adequate levels of adrenocortical steroids are required for suppression of oestrogen-induced stimulation of uterine metabolic activity<sup>1</sup>. Where these

Fig. 3. Augmentation by actinomycin D of circulating corticosterone in ovariectomized rats. Blood was collected from the abdominal aorta in heparinized syringes and centrifuged at 3,000 r.p.m. for 10 min. The separated plasma was promptly frozen. Afterwards, the freshly thawed plasma was analysed for corticosterone by the method of Silber as modified by Guillemin, R., Clayton, G. W., Smith, J. D., and Lipscomb, H. B., *Endocrinology*, 63, 849 (1958). The numbers of observations contributing to the mean plasma corticosterone values represented by successive bars, reading left to right, are 5, 8, 7, 5, and 8.

dose requirements are not met<sup>22</sup>, little or no acute inhibition of oestrogen activity may be evident. Levels of actinomycin D which effectively suppress RNA synthesis in mammalian tissues can produce the generalized stressful state associated with massive endogenous adrenocortical hypersecretion which has been demonstrated in the present investigations.

**RNA labelling.** As noted above, prior adrenalectomy virtually eliminated the inhibitory effect of actinomycin D on the stimulation of protein labelling by oestrogen. In contrast, removal of the adrenals had no comparable influence in relieving the antibiotic suppression of hormonally induced incorporation of carbon-14 from glycine or adenine into RNA (Table 1). As anticipated, the incorporation of isotope into DNA was negligible (<1 c.p.m./μg) in these experiments in which oestrogen was given 4 h earlier (well before stimulation of mitosis is evident<sup>1</sup>). The results recorded here do not support the assumption<sup>4,12,16</sup> that actinomycin D inhibits uterine responses to oestrogen by selective disruption of messenger RNA elaboration and, thus, protein synthesis. Instead, the results indicate that depression of the early uterine responsiveness to oestrogen after systemic administration of antibiotics such as actinomycin, puromycin and cycloheximide is due primarily to adrenocortical hyperactivity.

It is evident that the uterine growth response to oestrogen is associated with an increased formation within a few hours of RNA components which sediment in density gradient centrifugation as template<sup>8</sup> and ribosomal<sup>4,12</sup> fractions. However, expansion of the microcirculation to the uterus is induced by oestrogen through selective liberation of locally sequestered histamine within 30–40 seconds<sup>27</sup>. This very early effect may, by increasing the

## POTENTIAL EFFECT OF THE PLASMA PROTEINS ON DRUG DISTRIBUTION

By DR. B. K. MARTIN

Nicholas Research Institute, Ltd., Slough, Buckinghamshire

THE theoretical and practical aspects of the interaction of drugs with plasma proteins have been considered by Goldstein<sup>1</sup>, Edsall and Wyman<sup>2</sup> and others<sup>3–6</sup>, and it is generally accepted<sup>7</sup> that the 'protein-binding' of a drug in this manner can modify its distribution in the body and therefore influence both the dose-response relationship

and the rate of drug elimination. The work recorded here was undertaken to gain a more exact theoretical impression of the quantitative aspects.

The extent to which a drug is bound to a particular protein depends on the concentration of drug, on its affinity—which is quantitatively expressed by the asso-

ciation constant of the drug-protein complex ( $K_{sp}$ )—on the concentration of protein and its capacity—the number of sites ( $n$ ) available for drug binding on the protein molecule. When  $n = 1$ , then:

$$K_{sp} = \frac{[DP]}{[D_f] [P_f]} \quad (1)$$

where  $[D_f]$ ,  $[P_f]$  and  $[DP]$  represent respectively the molar equilibrium concentration of free (unbound) drug, free protein and bound drug. If  $\beta$  represents the fraction of the total drug in plasma which is bound to the protein, it

may be deduced<sup>1</sup> that:

$$\beta = \frac{[P_t]}{[P_t] + (1/K_{sp}) + [D_f]} \quad (2)$$

where  $[P_t]$  is the molar concentration of total protein.

In the present connexion, greater interest centres on that fraction of the drug which is free ( $\alpha$ ), for only the concentration of free drug contributes potential to its rate of transport across cell membranes. The rate of excretion of unchanged drug is related to the concentration of free drug rather than that of the total drug in the plasma. The

Fig. 1

Fig. 2

Fig. 3

Fig. 4

Figs. 1-4. The graphs are constructed from data calculated for four model drugs which interact with a single plasma protein and which have association constants ( $K_{sp}$ ) of  $1 \times 10^4$ ,  $1 \times 10^5$ ,  $1 \times 10^6$  and  $1 \times 10^7$ . The protein (albumin) concentration was  $5 \times 10^{-4}$  M, each protein molecule having one available site for interaction with drug. Plasma data (Fig. 1) were calculated from equation (8). The extended data (Figs. 2-4) relate to a man weighing 70 kg with plasma volume 3 l. and total body water 43 l., the free drug being uniformly distributed in total body water, with no binding or localization of drug in the tissues. If  $D_f$  and  $D_b$  are the respective molar equilibrium concentrations of free drug and bound drug in the plasma: amount of drug in body =  $42D_f + 3D_b$ ; percentage free =  $\frac{42D_f}{42D_f + 3D_b} \times 100$ ; percentage in plasma =  $\frac{3D_b}{42D_f + 3D_b} \times 100$

concentration of free drug in the tissues is in equilibrium with the free drug in plasma and hence the latter also influences both the rate of drug elimination by biotransformation and the magnitude of the pharmacological response.

Equation (2) may accordingly be transposed in terms of  $\alpha$  and—for simplicity in subsequent calculations—in terms of the dissociation constant  $K_{sp}$  ( $K_{sp} = [1/K_{sp}]$ ).

$$\alpha = \frac{[D_f]}{[D_t]} = \frac{K_{sp} + [D_f]}{[P_t] + K_{sp} + [D_f]} \quad (3)$$

It is also desirable to relate  $\alpha$  to the concentration of total drug in plasma ( $D_t$ ) rather than that of the free drug ( $D_f$ ), for it is the former which is normally measured clinically.

If  $K_{sp}$  and  $[P_t]$  are specified,  $\alpha$  may be calculated for selected values of  $D_f$  and the corresponding values of  $D_t$  may then be derived. Calculations were made for a series of model drugs which react with a single protein with values of  $K_{sp}$  ranging from  $1 \times 10^4$  to  $1 \times 10^7$ , with  $P_t = 8 \times 10^{-4}$  M, this being the typical concentration of albumin in plasma.

The foregoing considerations apply to an isolated, single-compartment system, that is, the drug and the protein occupy a common volume. While they provide an account of the quantitative changes in plasma, they give no indication of the changes in drug distribution in the body as a whole, or of the dosage-level at which they occur. The body must be considered at least as a two-compartment system, the plasma proteins being confined to the plasma volume while the free drug is distributed in a volume which approaches that of total body water. The plasma volume and the total body water constitute typically 4.3 and 60 per cent, respectively, of body-weight, so that on this basis the free drug in plasma is also in equilibrium with an additional volume which is 13 times that of the plasma volume. In this treatment the effect of any binding of drug in the tissues, with the consequent creation of additional compartments, has not been considered. The amount of drug localized in tissues can, however, be substantial and deviations from idealized behaviour will arise whenever any tissue attains a concentration of drug which is either appreciably higher or lower than the free concentration of drug in the plasma.

The calculations were therefore extended on the basis of the foregoing considerations and, in order to gain insight on absolute dosage values, they were applied to a man weighing 70 kg with a plasma volume of 3 l. and total body water equal to 42 l. The results are plotted in Figs. 1-4; each illustrates a different facet of drug distribution. Consider, for example, the model drug with  $K_{sp} = 1 \times 10^7$ ; increasing the dose or the amount of drug in the body from 1.4 to 1.9 mmoles (an increase of one-third) produces a ten-fold increase in the concentration of free drug in the body (Fig. 3), but the concentration of total drug in the plasma rises by only 10 per cent (Fig. 2). Whereas only 3 per cent of the smaller dose exists in its free form in the body, 22 per cent of the larger dose is free (Fig. 3); whereas 97 per cent of the smaller dose is confined in the plasma, only 79 per cent of the larger dose is in the plasma (Fig. 4).

The extended calculations for the whole body indicate that the binding of a model drug to the plasma proteins only has an appreciable effect on drug distribution if the drug has a  $K_{sp}$  greater than  $1 \times 10^4$ . The plasma data reveal that for the model drug with  $K_{sp} = 1 \times 10^4$  as much as 83.4 per cent of the drug in plasma can be bound, whereas the extended data show that at least 78 per cent of the drug in the body is free. As a consequence, the effect on the rate of elimination will be small, relative to drugs with  $K_{sp} = 1 \times 10^4$  or  $1 \times 10^5$ , when the percentage of the drug which is free can be as low as 22 and 2 per cent, respectively.

Differences in drug distribution arising from differences in  $K_{sp}$  are greatest at low drug concentrations, when  $\alpha$  approaches a minimum limit. This limit may be calculated from equation (3), for as  $D_f \rightarrow 0$ ,  $\alpha \rightarrow (K_{sp})/([P_t] + K_{sp})$ . At higher dosage-levels, differences in  $K_{sp}$  have a much smaller effect on the distribution characteristics, which converge towards a common pattern. No constant relationship can therefore be expected between  $K_{sp}$  and its effect on drug elimination or dose-response, for this depends also on the amount of drug present in the body. Elimination will always become progressively slower as elimination proceeds. In respect of the dose-response, there is a dosage-range within which small increases in dose produce relatively large increases in the concentration of free drug and as a result the biological response may also show a pronounced increase at this level. Again, these effects will only be prominent in the instance of drugs possessing a high  $K_{sp}$ .

The classical method of establishing the rate of elimination of a drug is to examine the decline of the plasma level of the drug with time. This involves the assumption that the plasma always contains a constant proportion of the total drug in the body. If the drug has a high  $K_{sp}$  value, this is not so. A plot of log plasma drug concentration against time may, over a limited period, appear to be linear, but the calculation of an elimination rate 'constant' from its slope can appreciably underestimate the rate of elimination, for the decline in the plasma level as a result of drug elimination is partly off-set by an increase in the proportion of the remaining drug which is located in the plasma (Fig. 4). The detailed consideration of this aspect will be the subject of a separate communication.

The rate of elimination of a drug is frequently observed to be proportional to the amount present in the body ( $D$ ), that is,  $-(dD)/(dt) = KD$ , where  $K$  is the first-order elimination rate constant. If a drug has a high  $K_{sp}$  value, this will not be so,  $K$  will progressively diminish and the half-life of the drug will increase as elimination proceeds because an increasing proportion of the remaining drug is bound to the plasma proteins (Fig. 3). A constant relationship will only exist in respect of the amount of free drug ( $D_f$ ), that is,  $-(dD)/(dt) = K'D_f$  and  $D_f = f(D)$ .

The theoretical considerations correlate well with the studies by Burns *et al.*<sup>6</sup> on phenylbutazone, certain features of which they explained in terms of the binding of the drug to the plasma proteins. Calculation<sup>4</sup> from the data of Burns *et al.*<sup>6</sup> indicates a  $K_{sp}$  for phenylbutazone of about  $1 \times 10^4$  with  $n = 1$ , and the experimental observations may then be compared with those calculated for the corresponding model drug.

In general, agreement is sufficiently close to suggest that a knowledge of the affinity and the capacity of the plasma proteins to complex with a drug can provide a useful guide to those aspects of a drug's behaviour which are related to its distribution. The statement that a certain percentage of a drug is bound to the plasma proteins is of limited value, whereas the determination of  $K_{sp}$  and  $n$ , though they may for a number of reasons lack precision, would be far more informative. Similar determinations in respect of the plasma proteins of relevant animal species, which often exhibit major differences<sup>6\*</sup>, would also permit a better correlation of the effects observed in animals with those expected in man.

## EFFECT OF 8-AZAGUANINE ON LEARNING OF A FIXED-INTERVAL SCHEDULE

By DR. ROBERT E. JEWETT, JAMES H. PIRCH and DR. STATA NORTON

Department of Pharmacology, Kansas University Medical Center, Kansas City

**M**ODIFICATION of RNA in neurones of the central nervous system has been suggested as a mechanism for the phenomenon of learning and memory<sup>1,2</sup>. This hypothesis has been tested by Hydén and Egyházi<sup>3</sup> by selective stimulation of neurones and analysis of RNA content and composition. These stimulated cells showed an increase in RNA content. Corning and John<sup>4</sup> have studied the effect of ribonuclease in blocking the retention of a conditioned response in regenerated planaria.

Drugs known to affect RNA metabolism have also been used to examine the hypothesis that RNA is modified in learning. Chamberlain *et al.*<sup>5</sup> have used 8-azaguanine to prolong the time for spinal fixation in rats; Dingman and Sporn<sup>6</sup> have used the same drug, injected intracerebrally, to modify water maze learning; and Flexner *et al.*<sup>7</sup> have studied the effects of intracerebral puromycin on learning of a Y-maze by adult mice. In general, the results of the experiments tend to support the concept that RNA is involved with learning and memory, and drugs capable of modifying RNA synthesis can adversely affect learning and memory.

The purpose of this investigation was to examine the effects of the drug, 8-azaguanine, in a conditioned discrimination study in rats using food rewards and two fixed intervals. Thirty female rats (140–150 g) of the *OPB* strain (Carworth Farms) were used in this experiment. Five animals were housed per cage (10 in. × 16 in. in dimension) and received food and water *ad libitum*. Food was withheld for 12 h before lever-pressing training.

Animals were trained to press a lever for a food reward in an operant conditioning apparatus twice weekly for 5 weeks. After the animals had learned to press for the food reward, continuous reinforcement for 15 min at each session was allowed. Twenty-five animals learned the lever-press food-reward association and were divided into control (6), placebo (7) and drug (12) groups, randomized for lever-pressing rate and body-weight.

After learning the lever press-food reward association, the following training schedule was started. In any one training session, called a trial, the programme started with rewarding the first lever press. Then a short interval (*SI*) was interposed before a second and then before a third reward could be obtained. The rewarded *SI*s were separated by a long interval (*LI*) before the sequence was repeated. Fourteen such sequences (*SI*, *SI*, *LI*) were presented in each trial. Training trials were conducted twice a week. Two trials were run at each of the following schedules: *SI* 1 sec, *SI* 1 sec, *LI* 30 sec; *SI* 2 sec, *SI* 2 sec, *LI* 60 sec; *SI* 3 sec, *SI* 3 sec, *LI* 90 sec; and *SI* 4 sec, *SI* 4 sec, *LI* 120 sec. These eight trials, during which the time intervals were progressively increased, will be referred to as Segment 1. Sixteen additional trials at the final schedule were given. The first eight of these trials will be referred to as Segment 2 and the last eight trials as Segment 3.

During Segment 1, the drug-treated animals received a suspension of 25 mg/kg of 8-azaguanine in polyethylene glycol 400 intraperitoneally in a volume equal to their weight in tenths of a ml. (that is 250 g  $\equiv$  0.25 ml.). Placebo animals received the vehicle alone in equal volume. All injections were given 30 min before the animals were tested in the conditioning apparatus. Animals were weighed immediately before injection.

Criteria were established for exclusion of rats from the study. If any animal (control or placebo) did not press at all, or did not complete two consecutive trials, no additional trials were given. If a drug-treated animal did not press at all, or did not complete two consecutive trials, no injections were made before subsequent trials. These animals (to be referred to as 8-azaguanine non-injected) were afterwards given trials which were equal in number to controls and carried on through the sequence.

Data were collected for the responses during all three segments. The equipment was programmed to record the number of lever presses during the short interval food reward period, the number of lever-presses during the 15-sec period after cessation of rewarded presses, and the total number of presses during the remainder of the long unrewarded interval (*LI*–15 sec). The number of presses for these individual parameters was averaged from the fourteen sets during each trial and converted to a response rate per minute.

The following parameters are included in this study: the response rate during the *SI*, the response rate during the 15-sec period, and the response rate during the *LI*–15 sec period.

All controls (6) completed the 24 trials. Two animals of the seven receiving placebo injections were excluded and had no additional training. Five of the original twelve 8-azaguanine rats completed the full 24 trials. Six of the seven animals excluded from injection were carried throughout the 24 trials. In order to evaluate toxicity, the weights of the animals were obtained throughout the trial period. No significant difference in weight gain between trials 1 and 24 was found for the various groups. Analysis by *t*-test did not demonstrate significant differences between control and placebo animals in any parameter of lever pressing or weight gain. Therefore, these groups were combined for analysis and will be referred to as controls.

**Comparison of controls with 8-azaguanine rats.** During the *SI*, the drug-treated animals showed a significantly slower rate of lever pressing during Segment 1 (Table 1). Drug-treated animals did not show significantly different response rates during the other segments. In the 15-sec interval, the 8-azaguanine-treated rats pressed significantly more slowly than controls during Segment 1. During Segment 2, no differences were found. However, in Segment 3, the response rates of the treated animals were significantly increased over control animals. The lever-pressing rate during *LI*–15 sec was also significantly slower during Segment 1. No significant differences were seen in this parameter during the final segments.

*Comparison of control and 8-azaguanine (non-injected) rats.* These animals demonstrated interesting differences from both control and 8-azaguanine animals. The *SI* lever-pressing rate was significantly slower during Segment 1, but not Segment 2 (Table 2). In Segment 3 these animals pressed significantly more slowly than controls. In both the 15-sec period and *LI-15 sec*, these animals showed no differences in Segments 1 and 2, but were significantly slower than controls in Segment 3.

*Comparison of 8-azaguanine and 8-azaguanine (non-injected) rats.* No differences in *SI* pressing rate were seen except during Segment 3 where the non-injected animals pressed at a significantly slower rate (Table 3). In the 15-sec period and the *LI-15 sec* the non-injected group pressed faster than treated animals, but during Segment 3 pressed at a rate significantly slower than treated animals.

*Potentiation of barbiturate sleeping time.* In view of the depressed rate of lever pressing observed when the treated animals were receiving drugs, two additional rats were given 50 and 200 mg/kg of 8-azaguanine intraperitoneally, and gross reduction in motor activity was observed.

In the light of these observations, potentiation of barbiturate sleeping time was studied. Twelve female rats of the same strain, age and weight as the experimental animals during Segment 1 were used. Thiopental (20 mg/kg) was injected intraperitoneally with either placebo (polyethylene glycol 400) or 25 mg/kg 8-azaguanine in polyethylene glycol 400. The animals receiving placebo did not show significant potentiation of sleeping time (time from loss to return of righting reflex), but those animals receiving 8-azaguanine showed significant potentiation over controls ( $P < 0.001$ ) and placebo ( $P < 0.025$ ).

The measure of learning of this discrimination procedure during the later trials may be considered to be a ratio of the lever-pressing rate during the *SI* food reward period to the rate during the 15-sec and *LI-15 sec* intervals. With repeated trials, the ratio would be expected to increase, that is, less lever pressing during the 15-sec and *LI-15 sec* periods compared with the *SI*.

The administration of 8-azaguanine during learning of the fixed-interval food-reward sequence appeared to decrease discrimination of the end of the *SI* as evidenced

by the significant elevation of the 15-sec lever-pressing rate over controls during Segment 3 (trials 17-24). The ratio of *SI* : 15 sec for the drug-treated group is 3.4 : 1 and for controls is 4.7 : 1. No significant disturbance of the rate during the *SI* or *LI-15 sec* was demonstrated at this time. The *SI* : *LI-15 sec* ratio was 25.7 : 1 for the drug group and 23.9 : 1 for the control group.

In contrast to the results of Dingman and Sporn<sup>6</sup>, who did not show depression of swimming ability in the water maze with 8-azaguanine, a significant depression of motor activity, as indicated by lever pressing, was demonstrated during the time of drug administration (Segment 1). This difference may be explained on the basis of motivation associated with the testing procedure, presumably less in our experiment, and on the basis that lever-pressing rate in a learned interval schedule is an easily disturbed measure of drug action<sup>6</sup>.

Chamberlain *et al.*<sup>5</sup> reported that no depression of activity or food and water intake was seen in rats receiving less than 50 mg/kg of 8-azaguanine intraperitoneally. In addition, these investigators showed a prolongation of the time for spinal fixation from 45 min to 70 min in rats receiving 8-azaguanine (50-200 mg/kg intraperitoneally, 1.75-8.75 h before postural asymmetry). These animals had received sodium pentobarbital 50 mg/kg for the surgery required to produce postural asymmetry<sup>5</sup>. This prolongation of the time required for spinal fixation may represent the direct depressant properties of 8-azaguanine as demonstrated in our experiments by depressed lever pressing rate and potentiation of barbiturate by 8-azaguanine. It has also been demonstrated that narcotic (barbiturate) sleep and hibernation reduce turnover rates of ribonucleic acids in rat brain and spinal cord<sup>10</sup>.

The 8-azaguanine non-injected animals showed significantly reduced responses in all parameters over control animals in Segment 3. The ratio of *SI* : 15 sec was 4.7 : 1 for the controls and 4.8 : 1 for the 8-azaguanine non-injected, indicating that learning of this parameter had not been changed. The *SI* : *LI-15 sec* ratio, however, demonstrated that the controls (23.9 : 1) pressed more than 8-azaguanine non-injected (34 : 1) indicating improved discrimination of this interval. Except for the *SI* in Segment 1, their pressing rates were the same as controls for all parameters during Segments 1 and 2. Since these animals had received 8-azaguanine during several trials before stopping injections, they may have had some degree of disturbed RNA metabolism. The possibility exists that enhanced RNA turnover, secondary to the reduction caused by drug, may account for the improved final performance. While these animals were originally excluded from additional injections by their refusal to press, they performed as well as controls with respect to the rate of pressing the lever. Their ratios compared with controls during Segment 2 were 3.1 : 1 and 3.2 : 1 respectively for *SI* : 15 sec and 12.9 : 1 and 12.7 : 1, respectively, for *SI* : *LI-15 sec*. These factors suggest that the observation of improved discrimination of the *LI-15 sec* interval during Segment 3 by this group is not due to lever-pressing rate alone.

## COSMOLOGY

### Creation Rate of Matter and the Heisenberg Uncertainty Principle

ACCORDING to the steady-state theory of the universe, new matter is continuously being created out of nothing<sup>1,2</sup>. The Heisenberg uncertainty principle, however, precludes the possibility of proving 'nothing', that is, absence of energy, unless the time of observation is infinite. Now, whatever the explanation of the famous red-shift phenomenon in astronomy, the result is always a finite volume for the observable universe; any observer, irrespective of his position, finds himself in the centre of an analogous observable universe. On the Sandage scale<sup>3</sup>, and assuming a Euclidean space for simplicity, extrapolation of Hubble's law yields a value of about  $1.3 \times 10^{10}$  light years for the radius ( $R$ ) of the theoretically observable universe.

The lowest energy quantum possible in a finite observable universe is limited by the largest possible wave-length,  $\lambda = 2R\pi$ ; thus, the theoretically lowest energy quantum in our universe has a mass  $m = \frac{h}{2R\pi c}$  (about  $3 \times 10^{-66}$  g)

and its period of vibration is  $\frac{2R\pi}{c}$  (about  $2.5 \times 10^{18}$  sec).

This length of time—about  $8 \times 10^{10}$  years—is considerable even on a cosmological scale, yet it is not infinite. Making use of the uncertainty relation  $\Delta E \times \Delta t = h$ , one finds that in our universe the theoretically minimal quantum mechanical energy fluctuation of vacuum around zero is equal to  $\pm \frac{h}{2R\pi\tau_0}$  every  $2.5 \times 10^{18}$  sec. It should be noted that

this process does not violate the energy conservation law. Obviously, to make use of this value, one must know how many times the process occurs in our universe. One can assume that this number equals the number of centres of analogous observable universes contained in our universe and that the shortest distance between such neighbouring centres cannot be less than the quantum mechanical 'minimum length',  $\lambda_0$  ( $1.32 \times 10^{-13}$  cm); this space quantization yields about  $3 \times 10^{13}$  such centres in our universe. Since the subsequent calculations refer to positive energy, the positive half of fluctuations will be taken into account.

On the foregoing assumptions the amount of matter created in the observable universe in each vibration period ( $\frac{2R\pi}{c}$ ) is:

$$\frac{h R^2}{3c\lambda_0^3} \quad (1)$$

where  $h$  is the Planck constant,  $R$  the Hubble radius of the observable universe,  $c$  the velocity of light in vacuo, and  $\lambda_0$  the quantum mechanical minimal length. The resulting value for the creation rate of matter is  $2.5 \times 10^{-46}$  g cm<sup>3</sup> sec<sup>-1</sup>. It seems of some relevance that Bondi<sup>4</sup>, using a different approach, found practically the same value for the rate of creation of matter.

In a system with continuous creation of matter and disappearance of matter over the horizon, according to Hubble's law the two processes automatically tend towards a state of equilibrium at which the mean density of matter in the universe ( $\rho$ ) is constant; using (1),  $\rho$  has the value:

$$\rho = \frac{\text{creation rate} \times R}{3c} = \frac{h}{24\pi^2 R c \lambda_0^3} = 3.3 \times 10^{-30} \text{ g/cm}^3;$$

thus, more exact determination of  $\rho$  might represent an observational test of (1).

To sum up, according to the present suggestion all energy, including matter, in our universe is continually being created as virtual energy on loan to be repaid after some  $8 \times 10^{18}$  years; the continuous creation of matter *ex nihilo*, and its disappearance into the void again, is interpreted by the Heisenberg uncertainty principle applied to a finite observable universe.

## GEOPHYSICS

### Infra-sonic Waves from Aurorae

DURING times of high geomagnetic activity, long-period acoustic waves have been observed at the ground<sup>1,2</sup>. The source of these atmospheric waves can be ascribed to auroral activity, particularly to the periodic heating around the  $E$ -layer in the polar upper atmosphere corresponding to pulsating types of aurorae<sup>3,4</sup>. Auroral pulsations, which are sometimes called auroral commutations, have periods that are quite similar to those of geomagnetic pulsations recorded simultaneously at the ground<sup>1,4</sup>. However, periods of auroral sonic waves are significantly longer than some of the auroral and geomagnetic pulsations recorded within the same period of geomagnetic activity.

The main purpose of this communication is first to point out the characteristics of auroral infra-sonics, and secondly to give some interpretation of the wave-form and periodicity of these atmospheric travelling auroral pressure waves which are observed at the ground.

Many kinds of atmospheric travelling pressure waves have been observed at the ground, particularly those produced by volcanic eruptions, large-scale explosions, earthquakes and meteorological disturbances such as tornadoes. These sounds from distant tropospheric sources are generally characterized by horizontal phase velocities near the local speed of sound, and by signal velocities (determined from the travel time from the source) of about the average sound speed of the atmosphere. These waves show irregular dispersion<sup>5</sup>. By contrast, sounds from aurorae have been shown to exhibit horizontal phase velocities usually greater<sup>1</sup> than 400 m/sec. They appear to radiate from the night side of the auroral zones<sup>1,2</sup>.

Examples of auroral pressure waves recorded at Fort Yukon, Alaska, and at the National Bureau of Standards in Washington, D.C., are shown in Figs. 1 and 2. Each line in the figures corresponds to a record from a microphone. The separate microphones for each figure were spaced 2–7 km from each other in a space array at ground-level. Fig. 1 shows clearly the apparent acoustic mode dispersion typical of auroral zone measurements<sup>6</sup> with short periods arriving first and the longer periods arriving later in time.

It is well known that there are two types of pressure waves in the atmosphere, which are called acoustic (sonic) and thermobaric (internal gravity) modes, respectively<sup>7,8</sup>. Periods of thermobaric waves are longer than  $\tau_B$ , which is called Brunt's period or Väisälä's period, while those of acoustic waves extend to short periods below  $\tau_A$ , which has been called the atmospheric acoustic resonance period<sup>9</sup> or modified acoustic stability period<sup>11</sup>.

15 JUL 60 N5 36

15 JUL 60

N3 37

Fig. 2. Record of infra-sonic waves during the geomagnetic storm on July 14, 1960, recorded in Washington, D.C.

For simplicity,  $\tau_A$  may be called Martyn's or Hines's period<sup>13</sup>. Angular frequencies ( $\omega = 2\pi/\tau$ ), corresponding to  $\tau_A$  and  $\tau_B$ , are given by:

$$\omega_A = \frac{\gamma g}{2c} \text{ and } \omega_B = \left[ \frac{g^2}{c^2} (\gamma - 1) + \frac{g}{c^2} \cdot \frac{dc^2}{dz} \right]^{\frac{1}{2}} \quad (1)$$

respectively, where  $g$ ,  $c$  and  $\gamma$  are the gravitational acceleration, sound velocity in the air and the ratio of specific heats of air,  $c_p/c_v \approx 1.4$ . If we assume constant molecular constitution, sound velocity is a function of atmospheric temperature  $T(z)$  only, that is:

$$c^2 = \gamma R T(z) \quad (2)$$

where  $R$  is the gas constant of air ( $2.87 \times 10^{-4} \text{ km}^2/\text{sec}^2 \text{ } ^\circ\text{K}$ ).

It should be noticed that in the isothermal atmosphere  $\tau_A$  is smaller than  $\tau_B$  (that is,  $\omega_A > \omega_B$ ) and no atmospheric wave exists between these two resonance periods, except the so-called Lamb's wave with propagation strictly limited to horizontal directions<sup>14</sup>. As shown by equation (1), if the atmosphere is unstable, that is, the negative temperature gradient exceeds the adiabatic lapse rate  $-g/c_p$ , then thermobaric oscillations do not occur ( $\omega_B$  becomes imaginary). Acoustic oscillations can propagate through the layers so long as stratification is sustained without collapse. This occurs when the lapse rate exceeds that of autoconvection,  $-g/R$ . On the other hand, as can be seen from equation (1), the more stable the layer, the shorter will be  $\tau_B$  (larger  $\omega_B$ ). Therefore, when the atmosphere is very stable, as in the upper stratosphere and in the thermosphere,  $\tau_B$  becomes less than  $\tau_A$ .

In short, from equations (1) and (2) it can be written that:

$$\omega_A^2 = \omega_B^2 + \Delta\omega^2 \quad (3)$$

where:

$$\Delta\omega^2 = \frac{g}{T(z)} \left[ \frac{g}{R} \left( \frac{2-\gamma}{2} \right)^2 \cdot \frac{1}{\gamma} - \frac{dT}{dz} \right] \quad (4)$$

Thus if  $\frac{dT}{dz} > 2.2 \text{ } ^\circ\text{K}/\text{km}$ , then  $\omega_A < \omega_B$  ( $\tau_A >$

Fig. 3. Atmospheric resonance frequencies  $\omega_A$  and  $\omega_B$  for the summer-time polar upper atmosphere

Fig. 4. Dispersion curve for atmospheric pressure-waves in the isothermal atmosphere ( $T = 800^\circ\text{K}$ ). Full and dashed lines indicate horizontal group and phase velocities

$\tau_B$ ), as is shown in Fig. 3 for a summer polar atmosphere<sup>13</sup>. Furthermore, in this case it can be shown that the waves with period between  $\tau_A$  and  $\tau_B$ , which are forbidden when  $\omega_A > \omega_B$ , can now propagate even in the vertical direction through these layers<sup>9,12,15</sup>.

On the other hand, as shown in Fig. 4, group velocities of acoustic waves and those of thermobaric waves decrease as the period of oscillation approaches  $\tau_A$  and  $\tau_B$ , respectively. Although in Fig. 4 these dispersions are shown only for an isothermal atmosphere ( $T = 300^\circ\text{K}$ ), one can present arguments for an increase of intensity of atmospheric pressure waves around these resonance periods because of the energy flux conservation. It has been shown that in the non-isothermal atmosphere there are several minima of group velocity in each mode of atmospheric waves<sup>16</sup>.

It should be emphasized that characteristic features of observed atmospheric waves indicate clearly that auroral pressure waves are essentially acoustic, while very-long-period pressure waves from other atmospheric disturbances are thermobaric. However, due to the existence of very stable layers in the actual atmosphere, ranges of the periods of the two types of atmospheric waves are overlapped at the minima of group velocity, one of which exists around periods of 3–5 min. Therefore, the occasional appearance of enhanced sinusoidal pressure waves from aurorae with periods around 5 min shown in Fig. 2 can be explained as follows: (1) During strong aurorae, not only the acoustic mode but also the thermobaric mode of atmospheric waves near the Brunt's period can be excited. (2) Short-period acoustic waves propagate through the wave duct, which is around the mesopause in summertime and more effectively around the tropopause in the winter-time<sup>17</sup>, with normal sound velocity and attenuate rather rapidly. Longer-period slower infra-sonic waves follow. (3) Thermally excited auroral thermobaric waves also propagate horizontally with inverse dispersion (that is, weak long wave first and strong short wave later). (4) At a certain distance the longest-period sonic waves can be overtaken by the shortest-period thermobaric waves. (5) Both waves then oscillate with the same period, at near Brunt's period.

The foregoing phenomenon is very similar to the so-called Airy phase, known in sound propagation under shallow water<sup>18</sup>. It should be noted that since the source of auroral excitation of atmospheric waves may sometimes have a wide horizontal area the two modes of atmospheric waves overlapping with opposite dispersion are not necessarily produced at the same point source. Details of this work<sup>19</sup> will be published in the *Proceedings of the Second Benedum Symposium, Pittsburgh*.

## PHYSICS

### Transmission of High-power Laser Light through Tapered Dielectric Tubes and Rods

THE transmission of high-power laser light was investigated for dielectric tubes and rods of a geometry schematically shown in Fig. 1. The measurements were performed with a Q-switched ruby laser as radiation source and with a calibrated 'rat's nest' bolometer (type Westinghouse) as energy measuring device. The energy in the laser beam could be varied between 0.07 and 1.0 J. The characteristic values for the laser pulse were 15 nsec rise-time and 30 nsec half-width. For all values of output energy, the beam showed a typical two-mode pattern. The energy distribution in each mode was approximately Gaussian. The beam was focused by a 6.4-cm focal length lens on to the centre of the entrance surface of the light guide. In all experiments the angle between the mode axes and the optical axis of the system was  $2^\circ$ . In the focal plane 99 per cent of the total energy was concentrated within a circular area of 1.5 mm diameter. 75 per cent of the beam energy was within an area of 0.5 mm<sup>2</sup>. The average power density within the 75 per cent limit calculates to about 20 MW/mm<sup>2</sup> for 0.5 J laser output. The light guides were drawn by glass-blowing techniques from materials with equal optical properties. The measurements are shown in Table 1.

Fig. 1. Schematic diagram of a tapered light guide. The beam is propagated from the right to the left. The measurements are given in Table 1.

Table 1. MEASUREMENTS OF THE TAPERED GUIDES

No.	Type	a*	b	c	d	e	f	g
(mm)								
1	Glass rod	75	32	21	3.0	0.9	—	—
2		148	34	20	3.5	1.0	1.8	0.5
3		140	40	15	6.2	1.0	1.5	0.2
4	Glass tube	96	42	13	6.2	1.1	3.8	0.9
5		78	31	14	3.8	1.3	2.7	0.9

\* Symbols as defined in Fig. 1. Maximum deviation from given value 2 per cent.

The energy transmission properties of a light guide can be characterized by: (1) The energy transmission ratio  $T = E_{out}/E_{in}$ , where  $E_{in}$  and  $E_{out}$  are the total energy transmitted through the entrance and the exit surfaces; (2) the directivity  $D = E_Q/E$ , where  $E_Q$  is the energy within the space cone  $\Omega$  symmetrically with regard to the optical axis,  $E$  is the total energy transmitted through the reference surface in the origo of the unit sphere; (3) the density coefficient  $\delta = T/S$ , where  $T$  is the energy transmission ratio as defined here and  $S$  is the radiating end surface of the guide. For a given  $\delta$ , both the energy and the power density can be calculated when  $E_{in}$  and the time characteristic of the laser pulse are known.

Experimental results for  $T$  and  $D$ , obtained with 0.5-J laser output, are given in Table 2. These values were reproducible to within 10 per cent. Control measurements with a laser output from 0.07 to 1.0 J did not result in any significant change of  $T$  and  $D$ . In tubes at least 99 per cent of the transmitted energy was found to be emitted from the bore. For both tubes and rods, the energy distribution along a diameter of the exit surface was sufficiently uniform to allow  $\delta$  to be calculated according

(5)  $\Omega=0.004$  sterad.

to the definition given here. A shift in the shape of the transmitted laser pulse was not recorded. Radiation damage in the guide material could not be observed. The power density that can be achieved by tapered guides seems to be sufficiently high to be useful in, for example, biological applications<sup>1</sup> when it is desired to irradiate small areas with a rather well-defined energy distribution and when it is of interest to replace conventional focusing systems by a more flexible light guide system.

GEOLOGY

Radiometric Age of the Serra Geral Formation

THE Serra Geral Formation consists of lava flows and is associated with dolerite dykes. It covers an area of about one million square kilometres in Uruguay and southern Brazil and is one of the largest volcanic masses in the world. From stratigraphic evidence its age could lie in the range from Upper Triassic to Upper Cretaceous; quite possibly it may be uppermost Triassic (Rhaetic) to Jurassic in age<sup>1</sup>.

This communication reports and comments on some samples originally collected for palaeomagnetic study<sup>2</sup> that have now been dated by the whole-rock potassium-argon method (Table 1).

Petrographically the rocks consist of:

- (1) *S-482*: Medium-grained (0.6 mm) olivine basalt with fresh, zoned plagioclase laths, fresh pale brown augite and scattered, partially serpentinized subhedral olivine. Occasional corroded, zoned xenocrysts of basic plagioclase are present. Extensively chloritized interstitial biotite is developed.
- (2) *S-21a*: Medium-grained (0.6 mm) basalt with fresh, strongly zoned plagioclase laths; augite and pigeonite, minor hornblende all margined by black dust. Occasional corroded, zoned xenocrysts of basic plagioclase are present. No chlorite is present.
- (3) *S-9a*: Medium-grained (0.5 mm) andesite with strongly zoned plagioclase laths in stellate aggregates.

Fig. 1. Sample localities and radiometric ages.

Hornblende and (?) biotite have been partially resorbed and are margined by black dust; augite is present in the groundmass. Weathering may have affected the alkali feldspars. Chlorite is absent.

(4) *U-20b*: Fine-grained (0.15 mm) andesite with fresh, zoned plagioclase laths, augite and partially resorbed hornblende extensively margined by black dust. Chloritic patches are common in the interstitial matrix.

(5) *U-22-A1*: Medium-grained (0.2 mm) pyroxene andesite with fresh, zoned plagioclase laths, rounded anhedral augite aggregates and partially resorbed hornblende margined by black dust. The interstitial matrix contains many chloritic patches.

(6) *U-30-A1*: Medium-grained (0.5 mm) pyroxene andesite with fresh, markedly zoned plagioclase laths, resorbed (?) hornblende, small subhedral aggregates of augite. The interstitial matrix contains what are probably patches of devitrified glass. Chlorite is absent.

Most of the potassium is probably present in the very fine-grained interstitial matrix as potash feldspar, biotite, etc. If these potassium-bearing phases have been altered since magmatic crystallization the K-Ar ages may be low. Chlorite, probably formed by hydrothermal activity, is present in the interstitial matrix of samples 1, 4 and 5; and weathered alkali feldspars are probably present in 3. These observations suggest that the most reliable ages are provided by 2 and 6, where chlorite and weathering effects appear to be absent.

According to the most recent geological time-scale<sup>3</sup>, all six samples are Upper Jurassic to Lower Cretaceous in

age. Five of the samples yield ages of about 140 m.y., and the sixth yields an age of 120 m.y. Although episodes of these ages have been confirmed by workers at the University of São Paulo<sup>4</sup>, it is not certain whether the determination on a chloritized sample at 124 m.y., reported here, represents a genuinely younger episode.

The Serra Geral Formation is one of several Mesozoic volcanic and hypabyssal episodes that are represented in the Gondwanic continents. When interpreting palaeomagnetic data these episodes have been assumed to be contemporaneous, but radiometric ages now show this assumption to be invalid (Table 2). Data for more refined interpretations are now being accumulated.

### Occurrence of Talc as a Clay Mineral in Sedimentary Rocks

TALC is a metamorphic and hydrothermal mineral which is found typically in the greenschist facies of metamorphic rocks, and in shear zones where it is an alteration product. Talc has recently been found to be widespread in limestones of many formations ranging in age from Devonian through Recent. Where present, it is almost invariably accompanied by chlorite; other clay minerals may or may not be present. The occurrence of talc has also been noted in sandstones and shales, but in these rocks it is extremely uncommon.

For identification, the clay minerals in the samples studied were separated from the rocks by routine methods. Limestones were treated with dilute hydrochloric or acetic acid and after washing were centrifuged. Sandstones and shales were disaggregated in an ultrasonic transducer. The 2-5 $\mu$  and < 2 $\mu$  fractions in the samples were obtained by standard settling techniques. X-ray diffraction patterns were taken with a Philips 'Norelco' unit, using copper radiation. Porous plates and glass slides were prepared. Table 1 gives X-ray diffraction spacings and intensity measurements for oriented talc samples from a metamorphic rock and from a limestone.

Ancient carbonate sediments in which talc was recognized are too many to be listed here, but include the following: Whiskey Creek Pass limestone (Deamoinean),

\* The number in parenthesis is the American Museum of Natural History sample designation.

La Veta Pass, Colorado; Beaverhill Lake Formation (Devonian), Swan Hills area, Alberta, Canada; Bell Canyon limestone (Permian), Guadalupe Mountains, West Texas; Green River Formation (Eocene), Piceance Basin, Colorado; and Pleistocene limestones of the Bahamas and Bermuda. The range of environments is open marine, reef, shelf, and non-marine, and includes both dolomitic and non-dolomitic rocks.

Griffin<sup>1</sup> found talc as a clay mineral in Recent unconsolidated sands of some of the beaches along the Gulf Coast. In the present study talc was recognized in Recent sand sediments from many areas, including beaches of Long Island, New York, bays of the Atlantic coast (Barnegat Bay, New Jersey) and Gulf of Mexico (Laguna Madre, Texas), and the Continental Shelf of the Atlantic Coast. Recent carbonate sediments in which talc was found include reef apron sands of the Red Sea (Gulf of Aqaba). Talc was also recognized in Recent salt lakes of West Texas.

The occurrence of talc as a clay mineral in evaporite deposits has been reported by others (Stewart<sup>2</sup>, Langbein<sup>3</sup>, Raymond<sup>4</sup>, and Dreizler<sup>5</sup>). Stewart<sup>2</sup> and Raymond<sup>4</sup> suggested a diagenetic origin for talc in the evaporitic sediments which they described, and Dreizler<sup>5</sup> noted that talc and other minerals in the Zechstein (Upper Permian) sediments which he studied are syngenetic or diagenetic. In non-evaporitic rocks, Millot and Palasus<sup>6</sup> reported talc from a dolomitic limestone. These authors favour a sedimentary (diagenetic) origin for talc in the limestone which they studied.

An authigenic origin is proposed for talc which occurs in limestone. The following observations support this inference: 1, talc favours limestone association and is extremely uncommon in other lithologies, except in evaporites; 2, it prefers chlorite association in limestones and also in metamorphic rocks (greenschist facies); 3, the associated chlorite is a magnesium chlorite; 4, the talc-chlorite ratio tends to be essentially constant, approximately 3 or 4 to 1; and 5, the talc-chlorite clay mineral suite is found in Pleistocene carbonates, such as in the Bahamas and in Bermuda, where influx of terrigenous debris was very minor. A reaction between Mg ions and silica may be responsible for talc formation.

Another three-layer (2:1) silicate of the talc group, pyrophyllite, has been reported in sediments. Diagenetic pyrophyllite has been recognized in Devonian shaly sands by de Segonzac and Millot<sup>7</sup>, in the Zechstein (Upper Permian) sediments of Germany by Fuchtbauer and Goldschmidt<sup>8</sup>, and in the Gothlandien-Devonian sediments of the Sahara by Rouge, Kulbicki and Kubler (oral communication to de Segonzac and Millot 1962, p. 3440). Ehlmann and Sand<sup>9</sup> reported pyrophyllite as an important constituent of shales, but believed that a hydrothermal or pneumatolytic origin is most likely for this mineral. Pyrophyllite was not found in the sediments I have examined.

This work was carried out at the Research Center of Pan American Petroleum Corporation; Mr. Truman Robinson prepared most of the X-ray patterns. Samples of metamorphic and hydrothermal talc were provided by the

Department of Mineralogy of the American Museum of Natural History.

## MINERALOGY

### Differential Thermal Analysis: Effect of Particle Size

SINCE differential thermal analysis involves the approach to equilibrium while the conditions are regularly changing (steady temperature increase), the recorded temperature of transformation depends on the reaction rate. This rate is affected by a catalyst. Rees<sup>1</sup> states that although the theory of catalytic action is only just being established, the dominant role of defects is generally accepted. More defects cause a decrease in the degree of crystallinity, which lowers the recorded temperature of transformation, as shown by the experimental results quoted by van der Marek<sup>2</sup>.

One of the many defects tabulated in the first category of a review on the significance of solid state defects by Rees<sup>1</sup> is the discontinuity at a perfect surface. This surface is similar to that of a mosaic, which is an arrangement of sub-parallel blocks less than one micron in size. The fact that nearly all perfect-looking crystals contain sufficient defects to be idealized as a mosaic was deduced from the reduced intensities of the observed X-ray diffraction reflexions compared with the expected intensities from a perfect crystal. These deductions agree with my earlier results<sup>3</sup>. I observed that any particle size range greater than one micron gave a similar recorded temperature of transformation for a particular reaction.

Since the surface area is inversely proportional to the particle size, the less than ten milli-micron fraction, which has a greater surface area than a mosaic, will produce a decrease in the recorded temperature of transformation. In order to check the reduction in the recorded temperature of transformation, it is necessary to obtain fractions possessing identical other defects. However, the only available methods of fractionation and grinding have been shown to yield unsuitable material<sup>4</sup>. It is expected, therefore, that other defects in this size range would make the plane surface defect appear to be insignificant.

In conclusion, the recorded temperature of transformation is not affected by any particle size range greater than one micron, and is unlikely to be materially affected by a sub-micron size range.

Another type of structure, or an impurity, may affect the reaction rate. The accelerating catalysts are called activators or promoters, while those that decrease the reaction rate are called poisoners or depressants. The technique of annealing will remove many other types of structure and their associated effects on the reaction rate.

## OCEANOGRAPHY

### High Interstitial Water Chlorinity in Estuarine Mangrove Swamps, Florida

RECENT investigations have shown that in coastal mangrove swamps of south-western Florida the average chlorinity of interstitial water contained in 2-4 ft. of unconsolidated sediment overlying bedrock is 2-12 parts per thousand greater than the average value of the overlying bottom water. General considerations would suggest that the two averages should be the same if chloride ions move across the sediment-water interface by molecular diffusion only.

During the rainy summer and autumn months these paludic swamps receive run-off from the extensive mainland swamps of southern Florida (Everglades) and consequently are flooded by fresh and brackish water of low chlorinity (0-15 parts per thousand). Throughout the following winter and spring drought months, marine water of normal (19 parts per thousand) to hyper-chlorinity invades the mangrove swamps. Submerged areas of the coastal swamps (excluding the mangrove forest) are typically 4-5 ft. deep at low tide<sup>1</sup>.

The high interstitial water chlorinity observed in the sediments of these swamps was initially interpreted as a palaeochlorinity<sup>2</sup>. The results of this investigation, however, have established that the difference between the average sediment-water and bottom-water chlorinity is too large to be attributed to palaeochlorinities. In some back-swamp areas the difference is as much as 12 parts per thousand; the typical contrast is 6-7 parts per thousand. In general, the difference between the two averages increases with distance into the coastal swamps; the difference narrows as the mainland fresh-water swamps are approached. The large discrepancy rules out a palaeochlorinity interpretation because the sediment column is so thin (2-4 ft.) that any systematic decrease (or increase) in bottom-water chlorinity of the magnitude required would soon bring about similar changes in sediment-water chlorinity owing to ionic diffusion. Only if a dramatic decline in average bottom-water chlorinity had recently occurred could a palaeochlorinity interpretation be maintained. Chlorinity measurements during the past decade and the average bottom-water chlorinity estimated from the molluscan fauna of the surface sediment indicate that this instigating requirement has not occurred.

Anomalous high interstitial water chlorinity may also result from an *in situ* mechanism which retains chloride ions within the sediment. Such a mechanism, involving compactive dewatering of the sediment and the development of a clay-water system behaving as a semipermeable membrane, has been described by Siever *et al.*<sup>3</sup>. Deposits of the coastal mangrove swamps, however, are thin, essentially lack clay minerals, and, except for peat layers, have necessarily undergone little compaction. Many of the sediments are quartzose and shelly sands and coarse silts and accordingly are generally permeable; the necessary semipermeable membrane would therefore appear to be absent.

Digging animals may mechanically enrich surface sediment in relatively high-chlorinity water. Burrowing would in general be most active at times when the swamps are occupied by marine water. Biological turn-over of the sediment, or penetration of bottom water into the sediment mass along burrows, would therefore tend to cause the entrainment of water having a chlorinity considerably higher than the average value for the area. Arguing against this is the fact that the number of marine or euryhaline burrowing organisms found in areas of low average water chlorinity—the areas of maximum difference in average bottom-water chlorinity and sediment-water chlorinity—is quite small<sup>4</sup>. Thus digging organisms would appear to account for only localized enrichment of chloride ions in interstitial waters.

Laboratory experiments by Callame<sup>4</sup> have shown that convective interchange across the sediment-water interface may rapidly implant water of relative high chlorinity in sediment saturated with water of lower chlorinity. Convective interchange involves the sinking, penetration, or entrainment of relatively dense bottom water into sediment containing water of lower density. In the mangrove swamps the density of the water is largely a function of, and directly proportional to, its salt content, of which chlorinity is a measure. The depth to which interchange may displace interstitial waters, and the rate at which interchange proceeds, is largely a function of the density difference and the permeability of the sediment. In this regard, anomalously high interstitial-water chlorinities in the coastal swamps are restricted to regions affected by rapid and pronounced seasonal changes in bottom-water chlorinity, that is, density. Consequently, sediment water which has had its density appreciably lowered by ionic diffusion across the sediment-water interface during the time that low-chlorinity water floods the swamps, is rapidly (1-4 months) covered by water of relatively much higher density as the dry season commences. *In situ* permeabilities of the loosely compacted peaty and shelly surface sediment<sup>1,2</sup> of the swamps are probably high enough to permit some sort of convective interchange. In the laboratory, permeabilities as high as 1-6 darcys have been measured on these sediments.

Even though supporting work has yet to be done, it is suspected that a convective interchange mechanism may account for the high interstitial-water chlorinity measured in mangrove estuarine sediments of south-western Florida. If this suspicion proves to be correct, then the interchange probably occurs during just the initial phase of the seasonal incursion of marine water into the coastal swamps. Following the gravity-induced interchange of bottom water and sediment water in the upper foot or so of the sediment, additional exchange of chloride ions across the sediment-water interface probably proceeds only by molecular diffusion. The diffusion-only stage is illustrated in Fig. 1 by the vertical distribution of interstitial-water chlorinity at station 62-100. These data represent conditions prevailing several months after marine water had completed its seasonal flooding of the swamps. Station

K2 (Fig. 1) was occupied in an area near that of 62-100, but during the low-chlorinity season.

## CRYSTALLOGRAPHY

### Preliminary X-Ray Data on Phenothiazine and Certain of Its Derivatives

Work is now in progress at the University of Cape Town to determine the complete molecular structures of phenothiazine and of certain of its derivatives, chlorpromazine base<sup>1</sup> and stelazine. The last-mentioned two are well-known drugs, used as tranquillizers and in the treatment of certain mental diseases, such as schizophrenia, and it is hoped that knowledge of their molecular structure will help in the understanding of their biochemical action in man.

**Phenothiazine.** Pale yellow needle-shaped crystals were prepared by evaporating slowly from a solution of carbon tetrachloride. Methyl alcohol was also a satisfactory solvent. X-ray rotation and Weissenberg photographs, using copper  $K\alpha$  radiation, have shown the unit cell to be orthorhombic with dimensions as given in Table 1. A previous report<sup>2</sup> gave cell dimensions in good agreement with those of this investigation.

The conditions for non-extinction were found to be  $h00, h = 2n$ ;  $0kl, k + l = 2n$ ;  $h00, h = 2n$ ;  $0k0, k = 2n$ ;  $00l, l = 2n$ . These lead to two possible space groups,  $Pna2_1$  and  $Pnma$ , the first of which is non-centrosymmetrical, and the second centrosymmetrical. The  $h00$  intensity data were measured on the microdensitometer, and the method of Howells, Phillips and Rogers<sup>3</sup> was applied. A statistical survey of the intensities of the reflexions gave an  $N(z)$  distribution very close indeed to the theoretical curve for a centrosymmetric projection, and the space group is therefore assumed to be  $Pnma$ .

The density of 1.35 implies 4 molecules per unit cell, in special positions.

**Chlorpromazine hydrochloride.** This substance was obtained in powder form from the May and Baker Laboratories, and crystals were formed by slow evaporation from a heated solution of benzene to which a few drops of ethanol had been added. The crystals were thin, transparent plates, forming in clusters, which were difficult to separate. They turned brown if exposed to light and were affected by exposure to X-rays when in air. Following a valuable suggestion made by the Société des Usines Chimiques, Rhône-Poulenc<sup>4</sup>, better crystals were obtained when the evaporation was carried out under nitrogen, and the deleterious action of the X-rays in air was considerably reduced by mounting the crystals in fine capillary tubes which were also filled with nitrogen and sealed.

X-ray rotation and Weissenberg photographs taken about the  $a$  and  $s$  axes have shown the unit cell to be monoclinic with the dimensions as given in Table 1.

The systematic absences were found to be  $0k0$  missing for  $k$  odd, and  $h0l$  missing for  $l$  odd, which lead uniquely to the space group  $P2_1/c$ .

X-ray powder data have been obtained for both phenothiazine and chlorpromazine hydrochloride, from powder photographs, and, in good agreement with these, from the automatic diffractometer.

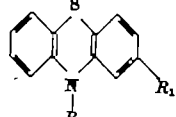

Fig. 1. Vertical distribution of interstitial water chlorinity measured in two sediment cores taken from the coastal mangrove swamps of south-western Florida. The vertical dashed lines indicate the approximate average ( $\pm 1$  part per thousand) bottom-water chlorinity at stations K2 and 62-100. Values inserted on either side of the arrows at the base of the lines show the range in monthly chlorinity averages.

Solvent	Carbon tetrachloride or methyl alcohol	Benzene + ethanol under nitrogen	Low b.p. petrol ether under nitrogen	Petrol ether	Low b.p. petrol ether

Note: The limits of error may be slightly larger than those quoted, as allowance was not made for film shrinkage.

**Chlorpromazine base.** Crystals were supplied by the Smith, Kline and French Laboratories (United States), the most suitable of which for single-crystal work were those which had been crystallized from low b.p. petrol ether. As in the case of chlorpromazine hydrochloride, the base was also susceptible to light, and to exposure to X-rays when in air, so it was re-crystallized under nitrogen in the dark from low b.p. petrol ether, and the crystals were mounted in nitrogen-filled fine capillary tubes.

X-ray rotation and Weissenberg photographs taken about the  $y$  and  $z$  axes gave an orthorhombic crystal system, with dimensions as given in Table 1.

The conditions for non-extinction were:  $0kl$ ,  $k = 2n$ ;  $h0l$ ,  $l = 2n$ ;  $hk0$ ,  $h = 2n$ ;  $h00$ ,  $h = 2n$ ;  $0k0$ ,  $k = 2n$ ;  $00l$ ,  $l = 2n$ ; which lead uniquely to the space group  $Pbca$ .

So far as we are aware, no crystal data have yet been published on chlorpromazine hydrochloride or on the base.

**Torecan** (see Table 1) (Santoz, Baale, Switzerland). Completely clear crystals of torecan were re-crystallized easily from petrol ether. From the reflexions observed:  $h00$ ,  $h = 2n$ ;  $0k0$ ,  $k = 2n$ ;  $00l$ ,  $l = 2n$ ; no other conditions; the space group was uniquely determined as  $P2_12_12_1$ . No further work on this compound is intended.

**Stelazine** (see Table 1). Pale yellow crystals were re-crystallized from low boiling point petrol ether. From the observed reflexions:  $h0l$ ,  $h = 2n$ ;  $0k0$ ,  $k = 2n$ ;  $hkl$ ,  $h + k = 2n$ ; two space groups,  $O2/c$  and  $Oc$ , were possible.

The intensity statistics test of Howells *et al.*<sup>2</sup> was made on the  $h0l$  X-ray data and this showed a non-centrosymmetric space group thus ruling out  $O2/c$ . The space group is therefore assumed to be  $Oc$ .

Approximately 1,800 reflexions have been recorded by the multiple-film technique and measured using a microdensitometer. A three-dimensional Patterson function has been calculated and is at present being interpreted.

## Growth Mechanism of Silicon Carbide

It has been suggested<sup>1,2</sup> that the growth of silicon carbide crystals takes place by the spiral-growth mechanism. Even though this theory, at the time, did explain the formation of the various polytypes, it did not account for the growth of the crystals in the 'a' direction. Recent X-ray work has shown the presence of new polytypes, the formation of which could not be explained by the screw-dislocation mechanism<sup>3,4</sup>.

This communication describes defects observed on some of the crystals which suggest that another mechanism could also play a part in the growth of silicon carbide. Examination of crystals under the optical microscope in some cases showed a series of steps around the edge ('root') which, during the sublimation-growth of the crystals<sup>5,6</sup>, was attached to the wall of the cavity. The steps were decreasing the thickness of the crystal in the direction of the root. In a few cases, such steps covered the whole basal plane.

Growth and evaporation spirals were also observed. The simultaneous presence of evaporation spirals and of steps is shown in Fig. 1a, while Fig. 1b shows part of the surface at a higher magnification. A surface similar in appearance was obtained by Young<sup>7</sup> on thermal etching of silver, when steps caused by evaporation propagated around an evaporation spiral. However, the structure shown in Fig. 1b could not have been formed by the same mechanism: the curvature of the steps suggests that they propagated from right to left; as the root of the crystal is to the left and the crystal is thinner there, the steps must have been formed by growth and not by etching. The interaction between the growth ledges and the spiral must have occurred due to line tension.

On some other crystals, the simultaneous presence of steps and of parallelepiped-shaped occlusions, appearing as light-coloured areas, was observed. The interaction of steps with two such occlusions is shown in Fig. 1c. The steps originating at two edges of the smaller occlusion were of relatively small height. To make them easier to locate, dashed parallel lines were drawn adjacent to them. Their curvature again suggests that they were advancing from right to left and must therefore have been caused by growth.

Steps were also observed to interact with defects that appeared as dark points in the photomicrographs (Fig. 1d). In such cases, the rate of advance of the steps was enhanced by the defects, suggesting the possibility that the defects were small spiral-growth hills.

It is difficult to visualize, even should critical concentrations of impurities be present<sup>8</sup>, how the spiral-growth

up to six months, although there was a greater proportion of polyhedra in the preparation with the most octo-*octearyl* alcohol. Preparations of this type with *cetyl* alcohol tend to develop needle-like crystals quite distinct from those particles shown in Figs. 1 and 2. The formation of polyhedra would not therefore appear to be a crystallization phenomenon.

Martynov<sup>6</sup> has pointed out that a non-spherical surface may have a lower surface energy than a spherical surface enclosing an equal volume. He found that a dodecahedron has a lower energy than spheres of equivalent volume below  $10^{-6}$  cm radius. However, non-spherical particles in our emulsions are at least two orders of magnitude larger than this (Fig. 2) and, while this effect cannot be discounted, we feel that an alternative explanation is required.

Manegold<sup>7</sup> described the formation of honeycomb or "polyhedral drop foams" in unstable close-packed emul-

Fig. 1. Photomicrograph of emulsion A, cooled while being subjected to ultrasonic irradiation. Diluted in glycerol containing 0.01 per cent methylene blue. 1 division,  $10\mu$ .

Fig. 2. Electron photomicrograph of emulsion B, allowed to cool undisturbed. Dispersed in bovine plasma albumin Fraction V (Armour) and sprayed on to grids coated with 'Formvar' and carbon films. When dry the grids were placed overnight in a holder over 0.5 per cent osmium tetroxide solution. The grids were then examined in an A.B.I. JEM3 electron microscope (method due to Dr. D. J. Craik, personal communication). 1 division,  $1\mu$ .

sions with disperse phase ratios in excess of 0.74, the theoretical limiting value for close-packing spheres of equal diameter. Our emulsion system has a disperse phase ratio of 0.225 and is apparently stable. Nevertheless, although the system as a whole cannot be close-packed, it appears likely that localized close-packing areas can exist, especially as the system has a wide range of particle sizes. This appears to be confirmed from examination of the undiluted emulsion and from electron photomicrographs when samples have not been adequately dispersed, for example, parts of Fig. 2. Under these conditions some particles or droplets are distorted by being close-packed and in this system these particles retain their original shape acquired during or following the emulsification stage. It is clear that the treatment of the liquid-liquid emulsion during cooling exerts an influence on the number of polyhedra which are seen in the subsequent solid-liquid dispersion. During dilution for microscopic analysis the particles in our system are solid and hence retain their shape. It seems likely that, in others, liquid particles may be able to retain their shape owing to the rigidity of the stabilizing interfacial film<sup>8</sup>. On the other hand, the disperse phase and the stabilizing interfacial film may be sufficiently fluid for the droplet to 'deform', or revert to a spherical droplet, as soon as the restraining conditions of tight packing are removed on dilution.

It may be concluded that some particles in an emulsion system may be irregular in shape. Whatever the cause, this irregularity can exist in systems where the disperse phase ratio is well below 0.74. In any investigation, therefore, of an undiluted emulsion it may not be tacitly assumed that all the disperse phase particles are spherical globules.

### Cadmium-Cadmium Chloride Solutions

THE nature of cadmium-cadmium chloride solutions is still the subject of considerable discussion, as also are the other metal-halide mixtures. The redox process between divalent cadmium and the species originating from the dissolution of metallic cadmium implies two electrons<sup>1,2</sup>, according to the following reaction:

This result agrees with a dissolution process the general scheme of which is as follows:

The most widely accepted values for  $n$  in the foregoing scheme are zero and unity; however, lately Topol and Landis<sup>3</sup>, on the basis of cryoscopic measurements by Grijthuis *et al.*<sup>4</sup> and a value of 7.22 kcal/mole for the heat of fusion of cadmium chloride, proposed values of 2 and 3.

In order to contribute to the solution of this problem, we investigated the distribution equilibrium of cadmium between molten cadmium chloride and a molten cadmium-copper alloy.

Weighed quantities of copper, cadmium and cadmium chloride were sealed in evacuated ampoules and main-

tained at 865° K for about 12 h. The ampoules were successively quenched and the two phases separated. The metallic phase was dissolved in nitric acid and the resulting solution analysed polarographically; the salt phase was dissolved in water, thus producing a cadmium chloride solution and a powdered cadmium residue. This residue was analysed in the same manner as the metallic phase and was found to contain some copper.

The copper content of the cadmium powders has been attributed to high-temperature oxidation of copper according to the reaction:

the equilibrium constant of which at 865° K is about  $10^{-4}$  (approximate value calculated from free-energy data<sup>1</sup>).

When the salt phase is dissolved in water, cuprous copper is reduced again to metal by the cadmium powder. This hypothesis is supported by the fact that the quantities of copper found agree well with those calculated on the basis of the foregoing equilibrium constant value. Therefore, the quantity (in moles) of cadmium metal found in the salt phase must be increased by an amount equal to half the quantity of the copper metal found, and the quantity of cadmium chloride must be decreased by the same amount. The mole fractions,  $N$ , of the components of the salt phase, calculated according to the foregoing statements, are given in columns 2–4 of Table 1 as a function of the mole fraction  $x_{\text{Cd}}$  of cadmium in the metal phase (column 1). The presence in the melt of the cuprous chloride is believed not to interfere seriously with the main equilibrium (2).

The ionic fractions,  $X$ , of the species  $\text{Cd}^{2+}$  and  $\text{Cd}_{(n+1)}^{2n+}$  are related to the crude mole fractions,  $N$ , of  $\text{CdCl}_2$ ,  $\text{Cd}$  and  $\text{CuCl}$  in the salt phase by the following equations, which are easily obtained from the stoichiometry of the reaction (2):

$$X_{\text{Cd}_{(n+1)}^{2n+}} = \frac{N_{\text{Cd}}}{N_{\text{CdCl}_2} - (n-1)N_{\text{Cd}} + N_{\text{CuCl}}}$$

$$X_{\text{Cd}^{2+}} = \frac{N_{\text{CdCl}_2} - nN_{\text{Cd}}}{N_{\text{CdCl}_2} - (n-1)N_{\text{Cd}} + N_{\text{CuCl}}}$$

The equilibrium ratio for the reaction (2) is thus:

$$K_s = \frac{X_{\text{Cd}_{(n+1)}^{2n+}}}{(X_{\text{Cd}^{2+}})^n \cdot a_{\text{Cd}}} = \frac{N_{\text{Cd}} \cdot [N_{\text{CdCl}_2} - (n-1)N_{\text{Cd}} + N_{\text{CuCl}}]^{n-1}}{[N_{\text{CdCl}_2} - nN_{\text{Cd}}]^n \cdot a_{\text{Cd}}}$$

where the ionic fractions of  $\text{Cd}^{2+}$  and  $\text{Cd}_{(n+1)}^{2n+}$  have been used in place of the activities on the hypothesis of the approximate constancy of the activity coefficients in the composition range investigated.

The activity values of cadmium in the metal phase,  $a_{\text{Cd}}$ , have been obtained from the literature<sup>2</sup> and are given in column 5, Table 1.

The values of the equilibrium ratios,  $K_s$ , calculated for the various values of  $n$  from the experimental data, are given in columns 6–9 of Table 1.

As can be seen, the values of  $K_2$  and  $K_3$  vary with the composition over a wide range, thus rendering very questionable the presence of the species  $\text{Cd}_2^{4+}$  ( $n=2$ ) and  $\text{Cd}_3^{6+}$  ( $n=3$ ). It is difficult to distinguish between the two species  $\text{Cd}$  ( $n=0$ ) and  $\text{Cd}_1^{2+}$  ( $n=1$ ) since the variations of  $K_0$  and  $K_1$  are of a similar order of magnitude; our data, however, seem to indicate, although not

in a conclusive manner, the presence in the melt of the species  $\text{Cd}_1^{2+}$ .

We thank Prof. L. Riccoboni for his advice. This work was supported by the Consiglio Nazionale delle Ricerche.

### Series Approximations to the Equation of Thermogravimetric Data

THE equation of the plot of thermogravimetric data is useful in kinetic analysis<sup>(1-12)</sup>, but since it contains an exponential integral, many workers prefer approximate expressions. The best balance of accuracy and convenience is achieved by the use of series taken to as few terms as possible, and it is the purpose of this communication to show which of four such abbreviated series approximations most nearly approaches this ideal.

In my notation<sup>1,12</sup>, the equation of the thermogravimetric data plot is:

$$g(h) = AE (BR)^{-1} p(x)$$

where  $h = (W-G) H^{-1}$

$$p(x) = e^{-x} x^{-1} - \int_x^\infty e^{-x} x^{-1} dx$$

and  $x = E (RT)^{-1}$

and where the specific form of  $g(h)$  depends on the type of kinetic process at hand<sup>1</sup>, and where  $A$ ,  $E$ ,  $R$  and  $T$  have their usual meanings as defined for the Arrhenius equation,  $B$  is the constant heating rate used in the analysis,  $W$  is the instantaneous residual sample weight and  $H$  and  $G$  are the total weight lost during the  $i$ th weight-loss step and the weight remaining after the step has been completed.

The series most commonly used in deriving approximations to  $p(x)$  are the asymptotic expansion (refs. 1, 2–7, 10–12) and Schlömilch's expansion (refs. 2, 8, 9). The expressions which result from taking these series to two and three terms are:

$$p(x) \sim x^{-1} e^{-x} \quad (\text{asymptotic, 2 terms}) \quad (\text{refs. 7, 10})$$

$$p(x) \sim (x-2)x^{-2} e^{-x} \quad (\text{asymptotic, 3 terms}) \quad (\text{refs. 3, 11})$$

$$p(x) \sim (x+1)^{-1} x^{-1} e^{-x} \quad (\text{Schlömilch, 2 terms})$$

$$p(x) \sim (x+2)^{-1} x^{-1} e^{-x} \quad (\text{Schlömilch, 3 terms}) \quad (\text{refs. 8, 9})$$

(It should be noted that the equations in refs. 8 and 9 are in error, owing to the use of the equivalent of  $1+2x$  rather than  $x+2$ .)

All these approximate expressions are convenient, save the second, which leads to an equation of the form:

$$x_s^2 (x-2_s)^{-1} \sim n$$

where  $n$  is a number derived from the experimental data, and  $x_s$  is evaluated at a particular value of  $T$ .

As for accuracy, the four approximate expressions can be compared<sup>12</sup> by taking the ratio between true and approximate values of  $p(x)$  for various values of  $x$ , as given in Table 1.

Table 1. RATIOS OF TRUE TO APPROXIMATE VALUES OF  $p(x)$

### Electron Spin Resonance Absorption of Solid Ion-radical Salt of *N,N,N',N'*-Tetramethyl-*p*-phenylenediamine and 7,7,8,8-Tetra-*p*-quinodimethane

For most charge transfer complexes, the ground-state can be described chiefly by a non-bonding structure  $DA$ , as the contribution of the dative structure  $D^+A^-$  is rather small, where  $D$  is the electron donor and  $A$  is the electron acceptor. However, it has been shown<sup>1-3</sup> for the complexes formed between aromatic diamines and substituted *p*- and *o*-benzoquinones that the dative or ionic state is the lowest one. These complexes may be regarded as salts, and can be prepared from salts,  $D^+X^-$  and  $M^+A^-$ , by a double decomposition reaction, where  $X^-$  and  $M^+$  stand for inorganic ions.

The solid complex of *N,N,N',N'*-tetramethyl-*p*-phenylenediamine (TMPD) with 7,7,8,8-tetracyano-*p*-quinodimethane (TCNQ) has been taken as ionic by Foster and Thomson<sup>4</sup> on the basis of its visible absorption spectrum. We prepared the 1:1 TMPD<sup>+</sup>=TCNQ<sup>-</sup> salt from Würster's blue perchlorate (TMPD<sup>+</sup>ClO<sub>4</sub><sup>-</sup>) and lithium salt of TCNQ (Li<sup>+</sup>TCNQ<sup>-</sup>) by the double decomposition reaction. In contrast to the well-known TCNQ anion radical salts<sup>4,5</sup> in which the positive ion is diamagnetic, this salt is composed of paramagnetic positive and negative ions.

Fig. 1. Schematic illustrations for the infra-red absorption spectra of the salt and its related compounds, TCNQ, Li<sup>+</sup>TCNQ<sup>-</sup>, TMPD<sup>+</sup>ClO<sub>4</sub><sup>-</sup>, and TMPD

Fig. 2. Variation of the electron spin resonance absorption intensity of the salt with temperature

The infra-red absorptions for the salt and its related compounds were examined by the method of Nujol mulls. The results are shown schematically in Fig. 1. By comparing the spectra with each other, it can be concluded that all the TCNQ and TMPD molecules are present as ion radicals in the salt. This observation is consistent with Foster and Thomson's conclusion for the complex prepared from neutral TMPD and TCNQ.

The electron spin resonance measurements were carried out on the freshly prepared polycrystalline sample of the salt. Temperature was varied by a flow of nitrogen gas at various temperatures between 150° and 300° K through the cavity. The sample showed a very sharp absorption of 6 gauss in over-all width, which was composed of three asymmetrically distributed lines. In the complex of *p*-phenylenediamine with *p*-chloranil, Matsunaga and McDowell<sup>6</sup> found that the electron spin resonance absorption consists of two peaks, which they assigned to each of the ionized component molecules. Recently, however, these two peaks have been shown to be due to the *g*-factor anisotropy<sup>7</sup>. In our case, the three peaks are also accounted for by the same cause.

The ratio of the electron spin resonance intensity of one pair mole of the salt to 2 moles of DPPH was found to be 0.17 at 23° C. If it is assumed that each ion radical in the salt contributes independently to the paramagnetism, this ratio should be one, because both component molecules are completely ionized. The observed ratio is inconsistent with this. Therefore it is likely that the paramagnetic state is an excited triplet state as has been suggested by Bijl, Kainer and Rose-Innes<sup>8</sup>. If the triplet state is thermally accessible, the variation of the electron spin resonance intensity  $I$  with temperature is given by:

$$I = C/T[3 + \exp(\delta/kT)] \approx \frac{C \exp(-\delta/kT)}{T} \quad (1)$$

where  $C$  is a constant and  $\delta$  is the separation between the singlet and triplet levels. As shown in Fig. 2, the observed temperature dependence is described by equation (1) with  $\delta = 0.075$  eV. Similar dependences on temperature for electron spin resonance intensity have been observed in the complexes of *p*-chloranil with diaminodurene<sup>4</sup> and *p*-phenylenediamine<sup>7</sup> with  $\delta$ -values of 0.16 and 0.13 eV, respectively.

The *g*-values for the salt and the component radicals were determined as follows:  $g(\text{salt}) = 2.0029 \pm 0.0001$ ,  $g(\text{TMPD}^+\text{ClO}_4^-) = 2.0032 \pm 0.0001$ , and  $g(\text{Li}^+\text{TCNQ}^-) = 2.0025 \pm 0.0001$ . The *g*-value of the salt agrees well with the mean of the *g*-values for TMPD<sup>+</sup> and TCNQ<sup>-</sup>. This indicates that the exchange interaction, which determines

the  $\delta$ -value, should occur between the unpaired electrons on TMPD<sup>+</sup> and TCNQ<sup>-</sup> radicals.

Although the assignment of the electron spin resonance absorption to the triplet state is a tentative one because of the lack of the detection of the  $\Delta m = \pm 2$  transition or single crystal work, it seems certain that a spin correlation exists between the unpaired electrons on the different ion radicals which enable the salt to be prepared. We also obtained the same results for the complex prepared from neutral components.

## BIOCHEMISTRY

### Dialysis of Oligosaccharides

IDENTIFICATION of oligosaccharide intermediates liberated during the enzymatic hydrolysis of a polysaccharide provides information on both the structure and mode of hydrolysis of the polymer. Isolation of these intermediates in good yield is facilitated if they can be removed from the enzyme site before further hydrolysis occurs. Perila and Bishop<sup>1</sup> accomplished this removal by hydrolysing a glucomannan in a dialysis sac to give a good yield of disaccharides (28 per cent) and lesser yields of tri- and tetra-saccharides (8 per cent each), and Timell<sup>2</sup> likewise hydrolysed a glucuronoxylan to moderate yields of oligosaccharides (none of these authors specified the grade of dialysis tubing used). Similarly, with a protozoal xylanase, we found that a convincing demonstration of the liberation of xylooligosaccharides of a degree of polymerization (DP) > 3 was only obtained when the xylan was hydrolysed by the enzyme with concurrent dialysis in 20/32 'Visking' tubing (Union Carbide Corp., N.Y.). Oligosaccharides of DP 3-5 are of relatively low molecular weight, but in our experience they dialysed at far slower rates than those reported for comparable peptides (see Table 2, Craig and King<sup>3</sup>). The dialysis of various oligosaccharides was therefore investigated in a simple dialysis chamber consisting of a piece of glass tubing (7 × 3.5 cm diam.) closed at one end with a sheet of opened-out dialysis tubing. The closed end dipped just below the external solution (10 ml.), the oligosaccharide solution (10 mg in 2 ml.; 3.3 cm<sup>3</sup> of membrane per ml.) was placed inside the chamber and both solutions were gently stirred with magnetic stirrers. At intervals, portions (100  $\mu$ l.) of external solution were removed for the measurement of dialysed oligosaccharide so that the time for the diffusion of half the initial oligosaccharide (half-escape time) could be calculated. Three grades of 'Visking' seamless cellulose tubing were used; 20/32, 36/36 and O-75 heavy wall.

The half-escape times obtained at room temperature (20° C) under these conditions for various oligosaccharides are given in Table 1.

With the maltodextrins a plot of these results against DP shows, for each grade of tubing, a linear increase in half-escape time with increasing DP. While the dialysis of these neutral oligosaccharides appears to be

Table 1. DIALYSIS OF OLIGOSACCHARIDES

Oligosaccharide (mol. wt.)	Solvent	Half-escape time (h) at 20° or (37°)		
		20/32	Tubing 36/36	O-75
Maltose (342)	Water	0.45	1.15	1.81
Maltotriose (504)	Water	0.87	1.66	2.31
Maltotetraose (666)	Water	1.25	—	2.76
Maltopentaose (828)	Water	1.60	—	3.00
Maltopentaose	Citrate-phosphate, pH 3.5	(0.80)	—	(1.70)
	Citrate-phosphate, pH 5.0	1.60	—	—
Maltopentaose	Citrate-phosphate, pH 5.0	1.55	—	4.00
Maltohexaose (990)	Water	1.88	3.10	—
Malto-octaose (1314)	Water	2.36	4.00	5.66
Cellopentaose (828)	Water	1.77	—	—
Isomaltopentaose (828)	Water	2.08	—	—
Raffinose (504)	Water	0.85	—	—
Trigalacturonic acid (646)	Citrate-phosphate, pH 7.0	2.30	—	—
Trigalacturonic acid	Citrate-phosphate, pH 3.5	1.40	—	—

independent of pH, the results with trigalacturonic acid suggest that the dialysis rates of acidic oligosaccharides are pH-dependent. It is evident that when good yields of oligosaccharides of DP > 2 are required from such dialysis digests the narrow 20/32 tubing, which would not be the logical choice for large-scale digests, should be used at as high a temperature as the enzyme will tolerate. Alteration of the porosity of dialysis tubing by stretching, as described by Craig and King<sup>3</sup>, might also give faster dialysis of these compounds.

### A Staining Method for Proteins and Dextran on Cellulose Acetate

AFTER the electrophoresis of human albumin labelled with iodine-131 in 0.06 M veronal buffer pH 8.6 on cellulose acetate, the strips were stained, dried, cleared in 'Dekalin' and scanned. The relationship between counting rate and dye uptake of amidoschwarz 10 B was linear up to, but not above, 30  $\mu$ g/cm, 0.5  $\mu$ l. of 6 per cent albumin applied evenly across 1 cm. Within this limit the method was suitable for the determination of albumin in human serum as percentage total dye uptake times total protein by the biuret method. Thirty-three sera checked using an internal <sup>125</sup>I-albumin standard gave results by this method and by the absolute albumin method of Lubran and Moss<sup>1</sup> which agreed within  $\pm 0.2$  g/100 ml. It was further observed that if the human eye could not see through the cleared band of stained albumin (or myeloma protein), then the strip was overloaded and in the non-linear range. No such simple safeguard existed for Ponocau S, where the relationship became non-linear above 15  $\mu$ g/cm, and indeed previous scans using this dye had underestimated the albumin. Accordingly, the following staining method was adopted.

Immediately after electrophoresis the strips are placed one at a time, applied surface downwards, into 0.25 per cent amidoschwarz 10 B in methanol, to each 100 ml. of which has been added 3 g of trichloroacetic acid to fix proteins immediately. After 5 min they are washed twice, for about 5 min, in methanol 90 parts: glacial acetic acid 10 parts, by which time the background is usually white. They are finally rinsed twice in methanol, and dried flat between blotting paper. Within 1-2 h they are ready for scanning, a considerable advantage over the aqueous

Fig. 1. Ten per cent 'Rheomacrodex' (above) and normal human serum with added 'Rheomacrodex' (below) applied at the heavy arrow and electrophoresed on cellulose acetate.  $SR/AR \times 1.00$  measures the relative mobility of  $\beta_1$ -globulin to albumin.

Ponceau S method, where drying takes many hours. The stain should be prepared afresh each week, or blue backgrounds occur.

During routine use a  $\delta$ -band was observed in a serum strip and was traced to the low molecular weight dextrans ('Rheomacrodex') which had been given to the patient (Fig. 1). Dextrans with no net charge are carried towards the cathode by endosmosis, thus marking the original line of application, and have long been used for the measurement of electrophoretic mobility relative to human albumin, which is taken as 1.00. In previous methods the dextran had to be separately identified<sup>1</sup>, but the foregoing accidental discovery offers a single method for fixing and staining both dextran and proteins. In the figure,  $\beta_1$ -globulin has a relative mobility of  $SR/AR \times 1.00$ . Applications at six different distances from the anode yielded results of  $0.47 \pm 0.01$ , which agree well with Wieme's value of 0.48 in agar.

'Rheomacrodex' is not fixed or stained by aqueous Ponceau S with trichloroacetic acid, but does stain with methanolic amidoschwarz 10 B without trichloroacetic acid, and this also works on chromatography paper, though longer washing is required. This may be applicable in the polysaccharide field.

### $\alpha$ -Helix in Fibrous Proteins

THE  $\alpha$ -helix was proposed by Pauling *et al.*<sup>1</sup> as a stable configuration of the polypeptide chain, and considerable support for this view was obtained from the X-ray diffraction patterns yielded by naturally occurring and synthetic polypeptides<sup>2,3</sup>. The diameter of the  $\alpha$ -helix was estimated to be about 10 Å and includes the contribution of the side-chains as well as the main-chains of the protein<sup>4</sup>. Direct proof of the existence of  $\alpha$ -helices in the globular protein myoglobin was obtained by Fourier synthesis methods<sup>5</sup>, and there is evidence suggesting that the  $\alpha$ -group of fibrous proteins contains rope- or cable-like assemblies of distorted  $\alpha$ -helices<sup>6,7</sup>.

In a recent investigation of the fibrillation induced in  $\alpha$ -keratin by irradiating iodine-treated wool with ultrasonics, it was found<sup>8</sup> that microfibrils  $\sim 75$  Å across were visible in electron micrographs of negatively-stained samples. In many cases the microfibrils had frayed into

fine protofibrils  $\sim 20$  Å across, an observation which is consistent with the notion of a rope-like assembly of the type proposed by Crick<sup>9</sup>.

Later it has been found that the protofibrils fray still further into either a pair of filaments of unequal diameter as in Fig. 1a or three filaments of equal diameter as in Fig. 1b. In view of the considerable support for Crick's structure from the X-ray data<sup>9</sup> there is good reason to suppose that the finest filaments, which are  $\sim 10$  Å in diameter, represent a direct record of the  $\alpha$ -helix by electron microscopy.

Fig. 1. Single protofibrils fraying into finer filaments ( $\times 600,000$ ).

It is too early for this evidence to be considered conclusive, but the simplest explanation of the situation in Fig. 1a is that one strand of a three-strand rope is detached from the other two, while in Fig. 1b all three strands are separate.

I thank Dr. R. D. B. Fraser for his guidance and help during this work.

### Electron Spin Resonance Spectra of Gamma-Irradiated Polycrystalline Glycollic Acid

THE electron spin resonance spectrum of glycollic acid irradiated at 77° K has been reported previously<sup>1</sup>, and consists of two doublets of unequal intensity, each with a separation of about 20 gauss. These were attributed to radicals having the unpaired electrons localized on oxygen atoms and coupling with the different hydroxyl protons.

Glycollic acid irradiated at room temperature gives an electron spin resonance spectrum consisting of a doublet with a separation of 25 gauss<sup>2</sup>. This was shown by deuteration studies, and later confirmed by single crystal experiments<sup>3</sup> to be due to the radical HO-CH-COOH.

We have irradiated polycrystalline glycollic acid at 77° K and observed the changes in spectrum as the crystals are warmed to room temperature. Glycollic acid was purified by repeated sublimation *in vacuo* at 45° C. It was then powdered and thoroughly pumped free of gas in a silica tube, which was finally sealed at a pressure of  $10^{-4}$  torr.

Samples received  $10^4$ – $10^5$  rads from a cobalt-60  $\gamma$ -ray source at a dose rate of  $1.4 \times 10^5$  rads h $^{-1}$ . While maintaining the crystals at 77° K, the electron spin resonance signal was removed from one end of the tube by annealing, and the acid transferred to this end. Electron spin resonance measurements at all temperatures were made using a Varian X-Band spectrometer, 'Model 4200', with accessories, signals being recorded as their first derivative.

Three different signals were observed as the temperature was raised from 77° K to 300° K. These are shown in Fig. 1. Fig. 1a was obtained at 77° K and reveals a doublet of 28 gauss splitting, which agrees with the spectrum published by Gordy *et al.*<sup>1</sup>, with the exception of a further small feature near the centre of the spectrum. This signal is stable for several days at 77° K, but changes gradually at 90° K and rapidly at about 120° K into a more complex spectrum (Fig. 1b), the principal feature of which is a triplet with a total separation of 43 gauss. A weaker signal is also present which appears to be another triplet with a separation of 35 gauss. This spectrum changes slowly at 140° K but rapidly at 170° K into the third spectrum (Fig. 1c). The signal is similar in all respects to that obtained on irradiation at room temperature, which has been shown<sup>2,3</sup> to be due to the carboxyhydroxymethyl radical  $\text{HO}\cdot\text{CH}\cdot\text{COOH}$ .

As the temperature is increased it is observed that the growth of one signal follows the decay of the other, indicating that one radical is reacting to form another. All changes caused by increasing the temperature are irreversible. With increasing dose the signals become stronger, but are otherwise unchanged.

The two triplets of Fig. 1b are probably due to the two radicals  $\cdot\text{CH}_2\cdot\text{OH}$  and  $\cdot\text{CH}_2\cdot\text{COOH}$ . The splitting observed in the weaker of the signals is very similar to that of the radical found on irradiating methanol<sup>4,5</sup>. The  $\cdot\text{CH}_2\cdot\text{COOH}$  radical has not been identified in poly-

crystalline material so that its isotropic electron spin resonance spectrum is unknown. The triplet, believed to be due to the  $\cdot\text{CH}_2\cdot\text{COOH}$  radical, is substantially less stable in this system than is the same radical in irradiated single crystals of malonic acid<sup>6,7</sup>. The change to the doublet which represents the  $\text{HO}\cdot\text{CH}\cdot\text{COOH}$  radical would then involve the abstraction by both these radicals of hydrogen atoms from glycollic acid molecules. The doublet observed at 77° K is possibly an ionic precursor of the type suggested previously, that is,  $\text{HO}\cdot\text{OH}_2^+\cdot\text{COOH}$  or  $\text{HO}\cdot\text{CH}_2^+\cdot\text{COOH}$ .

We have examined the products of the radiolysis at room temperature of crystalline glycollic acid and find some evidence to support the foregoing postulates. Methanol and acetic acid are both formed as major products, as would be expected from the abstraction reactions referred to above. Tartaric acid is also present in considerable amounts, by dimerization of the  $\text{HO}\cdot\text{CH}\cdot\text{COOH}$  radical.

In order to form  $\cdot\text{CH}_2\cdot\text{OH}$  and  $\cdot\text{CH}_2\cdot\text{COOH}$  radicals, it is necessary to eliminate  $\cdot\text{COOH}$  and  $\cdot\text{OH}$  respectively. Carbon dioxide is by far the main gaseous product of radiolysis, but as yet no product has been found to account for  $\cdot\text{OH}$  group removal. However, an adequate method for the analysis of water in this system has not been found and it could well be that the  $\cdot\text{OH}$  group is ultimately converted to water.

We thank the Pharmacy Research Trust of New South Wales for a scholarship to one of us (B. J. R.) and the Australian Institute of Nuclear Science and Engineering for financial support under contract 64/79.

### Coding of Polar and Non-polar Amino-acids

BIOLOGICAL properties of proteins depend on the higher levels of their structure, determined by the primary structure. As has been shown by Fisher<sup>1</sup>, the knowledge of the amino-acid composition permits in many cases the tertiary and sometimes the quaternary structure of the proteins to be predicted. The ratio of the polar and non-polar amino-acids seems to be a very important characteristic of the protein. The change of the relative numbers of the polar and non-polar amino-acids as a result of a mutation must produce big changes in the protein structure. The mutational exchange of a polar group for a non-polar one and vice versa must be more dangerous than the transition from one polar group to another or from a non-polar to another non-polar one. The well-known example is the transition from Glu to Val in the case of sickle-cell haemoglobin.

If these speculations are correct, then we have to look at the corresponding differences in the codons for polar and non-polar amino-acids. Let us take the codons of *m* RNA established by Nirenberg *et al.*<sup>2</sup> (the results published by Speyer, Ochoa *et al.*<sup>3</sup> do not differ much from those in ref. 2). These codons are shown in Table 1 together with parts of the nucleotides in all the codons corresponding to the said amino-acid. The compositions of the codons of the first and of the second group are different. This is shown in Table 2.

We see that the polar amino-acids are coded mainly by triplets containing adenine and cytosine, and the non-polar

G/C	0.61	1.05	1.64
U/C	0.87	1.50	2.35
G/A	0.33	0.73	2.00
U+G/A+O	0.82	1.02	2.20

amino-acids—by the triplets containing guanine and uracil.

This statement is very rough, being based on simple averaging. There are also few exclusions. However, the difference between the codons of the two groups is well pronounced.

It is easy to show that a mutation of the kind called transition means a transition from A to G or from C to U. The transition can therefore exchange a polar amino-acid for the non-polar one and vice versa. It is not always so in the case of transversion. We can think that the transitions are more dangerous than the transversions. Perhaps the probability of transitions is lower. Our knowledge of these problems is, as yet, very limited. But Freese<sup>4</sup> points out that 80 per cent of the spontaneous mutations of the T4-phage are not connected with transitions.

The causes of the differences stated here cannot be explained at present. The structures of A and C have common features—they contain an NH<sub>2</sub>-group at the greatest distance from the N-atom linked with ribose. U and G contain a CO-group at the same positions. Perhaps these differences in structure play some role in the interactions of the s-RNA with the corresponding aminoacyladenylate at the surface of specific enzyme.

The complete deciphering of the compositions of the codons and of the sequences of the nucleotides in them will make possible a more detailed analysis of this problem.

## Helix-rich Fraction from the Low-sulphur Proteins of Wool

MUCH has been learnt about the architecture of fibrous proteins such as myosin by controlled proteolysis and the application of physico-chemical and analytical techniques to the fragments obtained in this way<sup>1</sup>.

The low-sulphur proteins of wool (S-carboxymethyl-keratin A; SCMKA) resemble myosin in the relatively high proportions that assume the  $\alpha$ -helical conformation.

Harrap<sup>2</sup> found by optical rotatory dispersion measurements that SCMKA contains about 50 per cent  $\alpha$ -helix when dissolved in water and about 60 per cent when dissolved in 2-chloroethanol. It has now been possible, using controlled proteolysis, to prepare fractions containing greater amounts of  $\alpha$ -helix.

Solutions of SCMKA, prepared as described previously<sup>3</sup>, were digested with crystalline trypsin (1 mg to 100 mg SCMKA) or with pronase P (0.1 mg to 100 mg SCMKA) at pH 8.6 in the presence of 0.1 M CaCl<sub>2</sub>. The pH was kept constant and the progress of the reaction was followed by means of a pH-stat. With each enzyme the rate curve was characterized by an initially rapid digestion followed by a slower digestion. The digestion was terminated at the desired point, and the larger molecular species precipitated, by adjusting the pH to 4.2. The precipitate was recovered by centrifugation, dissolved in 0.05 M sodium borate, dialysed against a portion of the same buffer solution overnight and optical rotatory dispersion measurements made on the solution over the wave-length range 334 to 578 m $\mu$  using a Stanley photoelectric polarimeter.

When the optical rotatory dispersion data were plotted in terms of the Moffitt<sup>4</sup> equation, maximum values for  $-b_0$  were obtained when the initial rapid digestion was just complete. Pronase digestion produced fractions with  $-b_0$  values up to 520 corresponding with approximately 84 per cent  $\alpha$ -helix, whereas the product from tryptic digestion gave a  $-b_0$  value of 370, indicating an  $\alpha$ -helix content in water of only about 60 per cent. The maximum yield of the pronase digestion product prepared under these conditions was about 18 per cent by weight. The  $b_0$  values suggest that the wider specificity of pronase<sup>4</sup> enables the enzyme to rupture peptide linkages nearer to the helical portion of the molecule than is possible with trypsin.

Physico-chemical and analytical data relating to the helix-rich material will be published elsewhere.

## Synthesis of Cellulose by Enzyme Preparations from the Developing Cotton Boll

RECENTLY an enzyme system from mung bean seedlings was described which catalyzes the incorporation of radioactivity into cellulose from guanosine diphosphate D-glucose labelled with <sup>14</sup>C in the D-glucosyl moiety<sup>1</sup>. The extent of this incorporation was considerably stimulated by the addition of GDP-D-mannose to the reaction mixtures. This effect was later shown to result from the formation of some as yet uncharacterized polysaccharide, probably a glucomannan<sup>2</sup>. The synthesis of this compound also appeared to proceed at a rate many times that at which cellulose was formed by the same preparations. Sugars other than D-glucose, chiefly D-xylose or D-mannose, have been found associated with the cellulosic fractions of most plant species, but cotton fibres consist almost entirely of  $\beta$ -1,4 linked D-glucosyl residues<sup>3</sup>. It was therefore of interest to learn whether <sup>14</sup>C-labelled D-glucose from GDP-D-glucose <sup>14</sup>C could be incorporated into the cellulose of cotton fibres *in vitro*

and whether other polysaccharides were formed by the same cell-free enzyme system. The experiments reported here demonstrate that both these processes are brought about by enzymes isolated from the developing cotton boll.

Bolls at various stages of development were obtained from cotton plants (*Gossypium hirsutum*) through the courtesy of Drs. R. E. Johnson and F. T. Addicott, of the Department of Agronomy, University of California, Davis. The ages of the bolls were calculated from the time the flowers opened. The bolls were picked in the late afternoon, refrigerated overnight and sent to this laboratory in crushed ice the following morning. In each case enzymes were isolated from the plant material and incubated with the substrate on the day the material was received. Carpel walls were peeled from the bolls, and the segments, composed of seed hairs and immature seeds, were removed. In some experiments hairs were separated from the seeds by teasing out the seeds from the fibrous mass. The material was ground in a chilled mortar with sea sand and an equal weight of a buffer which contained 0.1 M *tris* HCl, pH 7.5, and 5 per cent polyvinylpyrrolidone (PVP)\*. The homogenate was squeezed through two layers of cheesecloth and centrifuged at 1,000g for 5 min; the precipitate was taken up in a small volume of the same buffer. The supernatant solution was centrifuged at 20,000g for 20 min and that precipitate was also suspended in a small volume of the PVP buffer. Both centrifugal residues were used as sources of the enzyme in most of the experiments.

<sup>14</sup>C-labelled substrates were synthesized and purified, and the incorporation of radioactivity into the product was estimated as described in previous publications<sup>1,2</sup>.

Like the cell-free preparations from other plant species and organs<sup>3</sup>, particles obtained from developing cotton bolls catalysed the incorporation of D-glucose-<sup>14</sup>C into cellulose only from GDP-D-glucose-<sup>14</sup>C. No incorporation of radioactivity could be observed when GDP-D-glucose was replaced in the reaction mixture by any of the following <sup>14</sup>C-labelled compounds: UDP-D-glucose, ADP-D-glucose, CDP-D-glucose, D-glucose 1-phosphate or D-glucose.

The extent of incorporation of radioactivity from GDP-D-glucose-<sup>14</sup>C into alkali-insoluble polysaccharide is shown in Table 1. The most active preparations were from bolls between 4 and 8 days old. The catalytic activities of particles precipitated with quite diverse centrifugal forces were about the same. This suggests that no discrete organelle is involved in this process.

In all cases the incorporation of label from GDP-D-glucose-<sup>14</sup>C into the product was stimulated by the addition of GDP-D-mannose to the reaction mixtures. Furthermore, the data in Table 2 demonstrate that when particles prepared from seed hairs alone were used, GDP-D-mannose still enhanced the incorporation of <sup>14</sup>C from GDP-D-glucose-<sup>14</sup>C into the alkali-insoluble product. By analogy with the results obtained earlier<sup>3</sup> this stimulation indicates the formation of another polysaccharide in addition to cellulose. The properties of the polysaccharide-synthesizing system from the cotton boll thus appear to be about the same as those of similar systems isolated from the roots and hypocotyls of mung bean seedlings<sup>4</sup>.

Cotton fibres are formed from specialized cells in the outer layer of the seed coat and are made up almost entirely of cellulose; thus it is surprising that enzyme preparations from these cells appear to catalyse the extensive synthesis of one or more polysaccharides other than cellulose. This phenomenon may be an artefact of the process *in vitro*, that is, the enzyme responsible for cellulose synthesis is perhaps unable to distinguish GDP-D-mannose from GDP-D-glucose, whereas GDP-D-

\* When PVP was omitted from the homogenizing buffer no synthesis of polysaccharide by the cell-free preparations could be demonstrated. Since cotton bolls contain large amounts of phenolic substances, PVP probably neutralizes the inhibitory effect of these compounds on isolated enzymes. This subject has been discussed at length by Hulme, Jones, and Wooltorton<sup>5</sup>.

Table 1. EFFECT OF AGE OF THE BOLL, PARTICLE SIZE, AND ADDITION OF GDP-D-MANNOSE ON SYNTHESIS OF POLYSACCHARIDE *in vitro*

Age of bolls (days)	Alkali-insoluble polysaccharide (c.p.m.)			
	1,000g fraction		20,000g fraction	
	- GDP-D-mannose	+ GDP-D-mannose	- GDP-D-mannose	+ GDP-D-mannose
4	190	390	200	655
6	170	340	220	610
8	306	560	220	545
12	85	330	180	415
16	120	315	180	530
21	120	200	30	95

Reaction mixtures contained 0.2 ml. of the particle suspension (derived from 2-4 g of immature cotton seeds and hairs) in 0.1 M *tris* HCl/5 per cent PVP buffer, pH 7.5,  $2 \times 10^{-4}$   $\mu$ moles (0.02  $\mu$ g; 6,000 c.p.m.) GDP-D-glucose-<sup>14</sup>C, and, when added,  $1 \times 10^{-3}$   $\mu$ moles GDP-D-mannose in a total volume of 0.25 ml. Mixtures were incubated for 1 h at 23-25° and the reaction stopped by immersing the tubes in boiling water for 2 min. Alkali-insoluble polysaccharide was isolated and its radioactivity estimated as described previously<sup>1</sup>.

Table 2. SYNTHESIS OF POLYSACCHARIDE *in vitro* BY ENZYMES PREPARED SEPARATELY FROM SEEDS AND SEED HAIRS

Source of enzyme	Alkali-insoluble polysaccharide (c.p.m.)	
	- GDP-D-mannose	+ GDP-D-mannose
Seeds	220	500
Seed hairs	180	460

The seeds (with most of the fibre removed) and the seed hairs from 14-day-old cotton bolls were homogenized separately in PVP buffer as described in the text. The reaction mixtures contained 0.2 ml. of particles precipitated at 20,000g and derived from 2 g of seed hairs or 4 g of seeds. The other conditions of the experiment were as given in Table 1.

mannose is not encountered by the enzyme *in vivo*, and hence that compound does not act as a glycosyl donor. If purification of the enzyme or enzymes involved in this synthesis can be achieved and the nature of the D-glucosyl acceptor can be elucidated, undoubtedly a more heuristic hypothesis will offer itself.

## Nucleoside Incorporation in Animal Cell Cultures

In a recent paper Cleaver<sup>1</sup> has investigated the uptake of nucleosides by tissue culture cells in physiological saline. From the results he states: "This suggests that the metabolism of these cells is markedly disturbed by brief exposures to a physiological saline and in particular the biosynthesis of the acid-insoluble fractions (for example, DNA and RNA) comes to a standstill. It has been assumed that under these conditions tritiated thymidine is incorporated into DNA and tritiated cytidine is incorporated into both DNA and RNA<sup>1,2</sup>".

This reference to my experiments<sup>1,2</sup> is misleading, and may give the impression that I incubated cell cultures in saline. In fact, as I stated clearly, in the procedure described<sup>1</sup> in my original papers<sup>1,2</sup> on nucleoside uptake, the cells were incubated in a mixture of three parts growth medium (containing 20 per cent serum plus amino-acid supplement) with one part Tyrode containing the nucleoside; thus the final concentration of serum in the medium was 15 per cent, which is in fact higher than that used (10 per cent) by Cleaver<sup>1</sup> in his control experiments.

# Alternative Pathway of Androgen Biosynthesis in the Human Adrenal Gland

THE major pathway of androgen biosynthesis in the human adult adrenal gland is well established: pregnenolone  $\rightarrow$  17 $\alpha$ -hydroxypregnenolone  $\rightarrow$  dehydroepiandrosterone  $\rightarrow$  androstenedione<sup>1</sup>. Previous results indicate that the adult adrenal gland converts a higher percentage of 17 $\alpha$ -hydroxypregnenolone than of progesterone to the product, androstenedione<sup>1</sup>. The data suggest that a pathway is possible which by-passes progesterone to form androgens: pregnenolone  $\rightarrow$  17 $\alpha$ -hydroxypregnenolone  $\rightarrow$  17 $\alpha$ -hydroxyprogesterone  $\rightarrow$  androstenedione. This report describes the results of an incubation to determine the significance of 17 $\alpha$ -hydroxyprogesterone in the biosynthesis of androstenedione. Cortisol synthesis was determined also, for comparison. An adenoma removed at operation from a 35-year-old female with Cushing's syndrome was used for these studies.

Adrenal adenomatous tissue slices were incubated in a Krebs-Ringer bicarbonate buffer (30 ml. buffer per g slice) which contained 7 $\alpha$ -<sup>3</sup>H-17 $\alpha$ -hydroxypregnenolone SA-L <sup>6</sup> $\mu$ o. per  $\mu$ mo and 4-<sup>14</sup>C-17 $\alpha$ -hydroxyprogesterone SA-L <sup>12</sup> $\mu$ o. per  $\mu$ mo separately, and in equimolar amounts (<sup>3</sup>H : <sup>14</sup>C 1:22:1). All flasks contained 0.2 ml. propylene glycol. Beef adrenocorticotrophic hormone (ACTH) (6 units) was added to certain flasks. The incubations were carried out for 3 h in an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide. <sup>14</sup>C or <sup>3</sup>H-labelled tracers were added to respective flasks for correction of manipulative losses. The methods of extraction, isolation and measurement of cortisol and androstenedione were as reported previously<sup>1,2</sup>. The radiochemical purity of the isolated steroids was determined by the constancy of the <sup>3</sup>H : <sup>14</sup>C ratio of the free compounds and derivatives following paper, or column<sup>3</sup> and thin-layer<sup>4</sup>, chromatography.

The <sup>3</sup>H : <sup>14</sup>C of cortisol determined after separation in the toluene: propylene glycol and Bush C systems<sup>4</sup> was 0.88 and 0.87 in the presence and absence of ACTH respectively. On the other hand, the <sup>3</sup>H : <sup>14</sup>C of androstenedione isolated from the same incubation media was 1.27 and 1.31.

The results of the identification data of cortisol and androstenedione are listed in Tables 1 and 2 respectively. The data indicate that 17 $\alpha$ -hydroxyprogesterone is an important intermediate in the biosynthesis of the adrenal androgen, androstenedione. The starting ratio of <sup>3</sup>H : <sup>14</sup>C of the  $\Delta^5$  :  $\Delta^4$  substrates is maintained in the isolated androstenedione, suggesting that the pathway from the 17 $\alpha$ -hydroxy- $\Delta^5$ -precursor may be via the intermediate 17 $\alpha$ -hydroxyprogesterone. However, the small amount of radioactivity in 17 $\alpha$ -hydroxyprogesterone precluded its identification. The addition of ACTH to this adenomatous slice system did not affect the <sup>3</sup>H : <sup>14</sup>C in androstenedione

Table 1. RADIOCHEMICAL PURITY OF CORTISOL DERIVED FROM 7-<sup>3</sup>H-17 $\alpha$ -HYDROXYPREGNENOLONE AND 4-<sup>14</sup>C-17 $\alpha$ -HYDROXYPROGESTERONE

but increased the efficiency of 17 $\alpha$ -hydroxyprogesterone as an intermediate in the biosynthesis of cortisol. These experiments suggest that the pathway 17 $\alpha$ -hydroxypregnenolone  $\rightarrow$  17 $\alpha$ -hydroxyprogesterone  $\rightarrow$  androstenedione is an important one for androgen biosynthesis in the adrenal adenomatous tissues studied.

## PHYSIOLOGY

### A Proposal for a Reference Standard Preparation for the Hypothalamic Thyrotrophic Hormone Releasing Factor

ANY programme which proposes to purify and isolate a biologically active material for which there is no specific physico-chemical mode of identification is on solid ground when it has at its disposal a bioassay and some reference standard preparation. The bioassay must be specific, reliable (reproducible), preferably sensitive, and able to demonstrate a linear increment of the measured metameter as a function of the log of the dose of the biological material injected. A reference standard preparation must be an isologous material which will give responses as a function of the doses injected, varying with slopes of that function identical to those observed when comparing the responses obtained with injection of purified materials along the course of the isolation procedure.

With the definition of a unit of biological activity, it is possible to follow quantitatively the various steps of a purification method and to calculate the specific activity (units/mg) of materials of various degrees of purity. A reference standard gives, furthermore, the possibility of comparing preparations obtained in various laboratories by calculating their specific activities in terms of a common unit. To our knowledge a reference standard has never been proposed for any of the hypothalamic hypophyseotropic hormones. Thus, the various programmes on the purification of the hypothalamic releasing factors have so far reported the biological activity of the material prepared by quoting the dry weights for minimal effective doses or by showing the very responses obtained in the various bioassays or tests (adrenal ascorbic acid depletion, plasma or adrenal corticosterone concentrations, ovarian ascorbic acid contents or variations, uterine weights, plasma iodine-131 radioactivity, etc.).

The inherent limitations to such procedures for quantitative studies on a purification programme are all too obvious, and the use of the (corresponding) pituitary hormone standards as reference preparations to express the hypophysiotrophic activities is not a satisfactory answer to the problem. The activity of the hypophysiotrophic factors is transhypophysial, that is to say, their effects are mediated by an adrenohypophysial response, which would not be reflected or reproduced with the use of pituitary hormone standards. This is even more evident where the hypophysiotrophic activities are examined by measuring the plasma concentrations of circulating pituitary hormones, as can now be done for adrenocorticotrophic hormone (ACTH), luteinizing hormone (LH) or thyrotrophic hormone (TSH).

We propose and describe here a reference standard preparation of hypothalamic origin to be utilized in the purification of the hypothalamic factor TRF related to the secretion of thyrotrophin. This material is the lyophilized fraction with TRF-activity obtained by gel-filtration through 'Sephadex G25' of the 2 N acetic acid extracts of ovine hypothalamic tissues, as in the conditions originally described<sup>1</sup>. This material is crude enough to be reasonably stable when kept as a dry powder in a vacuum at +4°C or at room temperature. It is devoid of TSH activity and has no vasopressor activity<sup>1</sup>. It gives a linear response in the bioassay as a function of the log of the dose of material injected<sup>1,2</sup>. The linear functions relating responses to log doses of the standard are parallel to those obtained with purified TRF.

It is proposed that the biological activity (stimulation of the release of TSH) of 1.0 mg of this preparation be attributed the value of 1.0 unit. The assay used to characterize this TSH-hypophysectrophic activity is the bioassay described earlier by Yamazaki, Sakiz and Guillemin<sup>3</sup>, or a recent modification thereof in which the pre-treatment with thyroxine (see ref. 2) is omitted. Approximately six months ago, several grams of a material with TRF activity prepared as above were set aside from our current purification programme and considered as a reference standard. So far we have no evidence of loss of biological activity. In the bioassay used here<sup>4</sup> this TRF preparation gives a statistically valid response with doses  $\leq 1.0$  mg or 1.0 unit, with a linear segment of the response curve up to 10 units. The use of this reference preparation over several months has shown us that the sensitivity of the bioassay is quite variable from one group of animals to another.

Similar preparations as internal standards could be made simply in the various laboratories interested in the purification of hypothalamic hypophysectrophic factors. For reference standard preparations of CRF (corticotrophin releasing factor) and LRF (LH-releasing factor) we have been investigating the same type of material (that is, the 'Sephadex G25' concentrate of CRF and LRF) and an even simpler material, that is, the boiled 0.1 N hydrochloric acid extract of rat stalk median eminence. Two problems have not been satisfactorily resolved as yet: (a) the linearity of the pituitary secretion of LH as a function of the dose of injected LRF (of whatever origin); (b) the stability over several months of the LRF- and CRF-activity in the crude extracts so prepared.

To facilitate meaningful comparisons, between investigators, for sensitivity of biological assays, specific activity of various preparations, etc., our laboratory will consider making available on request aliquots of the TRF reference preparation described here to allow expressing any other local standards in terms of a common unit.

### Plasma Disappearance of Various <sup>125</sup>I-labelled Growth Hormone Preparations in Man and Rabbit

STUDYING the properties of pepsin-digested bovine and sheep growth hormone<sup>1</sup> it was found that one fraction of the digest possessed electrophoretic and immunological properties similar to human growth hormone. The purpose of the present work was to compare the *in-vivo* behaviour of untreated and digested sheep growth hormones with the human hormone. This was tested by

following the kinetics of the plasma disappearance of the radio-iodinated hormones.

The growth hormone preparations used were: human growth hormone (HGH), sheep growth hormone (SGH, batch S<sub>1</sub>) and chymotrypsinized bovine growth hormone (BGH-CY-75). The sheep growth hormone was used untreated or after pepsin digestion<sup>1</sup>. The labelling procedure with <sup>125</sup>I was performed according to Hunter and Greenwood<sup>2</sup>. By this method we obtained a specific activity of growth hormone in the range of 50–100  $\mu$ Ci/ $\mu$ g. The patient material comprised 12 adolescent boys and 2 girls. The day before, and on the morning of the experiment, they received stable iodide (Lugol solution) in order to block the thyroid gland. The experiments were performed in the fasting state and labelled growth hormone preparations were administered intravenously in a dose range of 20–50  $\mu$ Ci per patient. Blood samples at predetermined intervals were collected in heparinized test-tubes for 3–4 h. Aliquots of the plasma were counted in a well-type NaI ('TI') scintillation detector, and the proteins were precipitated by a 20 per cent solution of cold trichloroacetic acid (TCA). The values of the TCA-precipitable radioactivity were compared with the injected dose and the ratio was plotted on a semilogarithmic paper against time. Each study group comprised four patients. Serum albumin was given only to two.

The plasma disappearance curve showed three phases: an extremely fast-mixing phase which was followed by a second phase (designated 'A') and a slow third phase (designated 'B'). The results of the individual experiments were in good agreement. The plasma disappearance of the various labelled growth hormones studied and of radio-iodinated human serum albumin (RISA) is illustrated in Fig. 1.

For HGH the  $t_{1/2}$  of phase A ranged between 20 and 30 min. This half-time correlates well with the metabolic degradation rate of endogenous HGH<sup>3,4</sup> and with other studies using HGH-<sup>125</sup>I (refs. 5 and 6). Phase B showed a slower plasma disappearance with a  $t_{1/2}$  ranging between 150 and 180 min. This phase is at present considered to represent the fate of 'damaged' HGH. The plasma disappearance of radio-iodinated SGH was in the similar range with HGH-<sup>125</sup>I: phase A -  $t_{1/2}$  = 20–25 min; phase B -  $t_{1/2}$  = 120–130 min. The similarity of the plasma disappearance of HGH and SGH, in what is considered to represent the metabolic phase of HGH, is of interest as SGH is biologically not active in man. The plasma disappearance of <sup>125</sup>I-labelled SGH after pepsin digestion showed a prolongation of both phases, A:  $t_{1/2}$  = 55–70 min and of phase B:  $t_{1/2}$  = 200–250 min. No significant amounts of TCA-precipitable radioactivity were found in the urine collected for 24 h.

A series of experiments was performed in rabbits. Groups of three rabbits were injected intravenously with labelled untreated SGH, pepsin-digested SGH, chymotrypsinized BGH and RISA. As in the human subjects, three phases of the plasma disappearance of the labelled hormones were found. The results are summarized in Table 1.

The metabolic phase A of HGH in the rabbit as found in the present study and by Salmon *et al.*<sup>7</sup> shows a disappearance range comparable to that in man. Though both HGH and BGH or SGH are metabolically active in the rabbit, the metabolic phase of SGH is slightly longer than that of HGH. The significance of the prolonged second-stage disappearance curve (phase B) remains an open question.

Table 1. PLASMA DISAPPEARANCE IN THE RABBIT OF <sup>125</sup>I-LABELLED GROWTH HORMONE

Hormone preparation	No. of rabbits	Phase A - Range of $t_{1/2}$ (min)	Phase B - Range of $t_{1/2}$ (min)
HGH	3	20–25	120–180
SGH	3	30–40	150–180
SGH pepsin digested	3	40–45	250–280
BGH chymotrypsin digested	1	40	200

Fig. 1. Plasma disappearance in man of  $^{125}\text{I}$ -labelled growth hormones

### Spinal Cord Convulsions in the Developing Rat at Altitude (12,470 ft, 3,800 m)

PREVIOUS investigations in this laboratory have demonstrated that maximal electro-shock seizure responses are more severe in adult rats brought to high altitude<sup>1</sup> and in developing rats born at high altitude<sup>2</sup> than in corresponding sea-level controls.

Spinal reflex systems play an important part in integrating maximal seizure discharge into the motor pattern<sup>3</sup>. The spinal cord of the rat matures, functionally, more rapidly than do higher centres of the central nervous system<sup>4</sup>. In view of this, the present study was undertaken to determine whether the spinal cord is more active in rats born and maintained at altitude than in their sea-level controls.

This study was done at the University of California, Berkeley, elevation 250 ft. (76 m), 750 mm mercury, and at the Barcroft Laboratory, White Mountain Research Station of the University of California, elevation 12,470 ft. (3,800 m), 480 mm mercury.

Barcroft Laboratory has a Long Evans rat colony. Sea-level rats are continually taken to the station for

breeding. The animal quarters at altitude are similar to those at sea-level as regards food, caging, temperature and lighting.

The experimental animals were divided into 2 different age groups, that is, 11- and 28-day-old rats. The brain of 11-day-old rats is less mature than that of 28-day-old rats<sup>5</sup>. The following numbers of rats were used: in the 11-day-old group, 13 sea-level controls and 12 second-generation rats born at altitude ( $F_2$ ); in the 28-day-old group, 19 sea-level controls and 12  $F_2$  rats.

Spinal cord convulsions were produced by direct electrical stimulation of the cord as described by Esplin and Preston<sup>6</sup> and modified by Vernadakis<sup>7</sup>. All rats were decapitated at an upper cervical level and a stimulating electrode, cathode, was inserted 4–5 mm into the spinal cord. The anode was attached to the exposed tissue of the neck. Square wave stimuli, 1 msec in duration, at an intensity of 30 V and a frequency of 100 pulses/sec were delivered within 10 sec after decapitation. Duration of spinal cord stimulation was 10 sec. A

series of electronic timers were activated by the stimulator and measured in msec the duration of each of the seizure components—tonic flexion and tonic extension.

Significance of differences between sea-level and altitude-exposed animals was calculated by the *t*-test.

Table 1. DURATION (SEC) OF SPINAL CORD CONVULSIONS IN TWO DIFFERENT AGE GROUPS OF YOUNG  $F_2$  RATS AT SEA-LEVEL OR AT ALTITUDE (12,470 ft)

Age	Spinal cord convulsions (duration of phases in sec)	No. of animals	Sea-level controls	No. of animals	$F_2$ rats born at 12,470 ft.
11 days of age	Flexion $\uparrow$	13	1.30 $\pm$ 0.10*	12	2.50 $\pm$ 0.25 <0.001
	Extension $\uparrow$		8.85 $\pm$ 0.30		7.17 $\pm$ 1.15
28 days of age	Flexion $\uparrow$	19	1.96 $\pm$ 0.54	12	1.29 $\pm$ 0.07
	Extension $\uparrow$		4.14 $\pm$ 0.07		9.69 $\pm$ 0.09 <0.001

\* Mean  $\pm$  standard error.

<sup>†</sup> Values based on *t*-test for significance of differences between sea-level and altitude rats.

Durations of flexion and extension in 11- and 28-day-old rats born at altitude and sea-level controls are presented in Table 1. The duration of flexion in 11-day-old altitude-born rats was significantly longer and duration of extension did not change significantly when compared with sea-level controls (Table 1). Duration of extension was significantly increased in the 28-day-old rats born at altitude as compared with sea-level controls; duration of flexion was decreased but not significantly (Table 1).

The shorter the duration of flexion and/or longer the duration of extension the more severe the convulsion and vice versa<sup>8</sup>.

The longer flexion and the shorter extension in 11-day-old altitude rats indicate a decreased activity of the spinal cord. In contrast significantly longer extension of the 28-day-old rats indicates more intense activity of the spinal cord. It is suggested that the longer flexion in 11-day-old altitude-born rats may be due partially to a delay in maturation of the spinal cord. Vernadakis has shown that flexion is longer in less mature rats<sup>7</sup>. The longer extension in 28-day-old altitude rats indicates an increased reflex excitability of the spinal cord. These observations are in agreement with previous studies from this laboratory. It was found that development of the central nervous system as assessed by brain electrical stimulation is delayed at altitude, and once maturation is achieved increased excitability is observed<sup>9</sup>.

It can be concluded that delay in central nervous system maturation in  $F_2$  rats born at an altitude of 12,470 ft. (ref. 2) may be attributed, in part, to changes in the function of the spinal cord.

# Mechanism of Muscular Paralysis by Insulin with Particular Reference to Familial Periodic Paralysis

OFFERIJNS *et al.*<sup>1</sup> have shown that insulin exerts a paralyzing effect on the isolated diaphragm of rats fed on a potassium-free diet. A close similarity seems to exist between this experimental muscle paralysis in rats and the familial hypokalaemic periodic paralysis in man. In both cases, the contraction in response to indirect as well as to direct stimulation is depressed, insulin and low potassium concentration in the extracellular fluid are important causative factors, and the contraction is restored when the extracellular potassium concentration  $[K]_o$  is increased. These facts led us to investigate further the mechanism of the muscular paralysis induced by insulin.

Albino rats weighing about 90 g were fed for more than three weeks on a potassium-free diet *ad libitum*. The composition of the potassium-free diet was similar to that used by Offerijns *et al.*, and consisted of sugar, casein, soybean oil, salt mixture and vitamins. Phrenic nerve-diaphragm preparations were dissected out and placed in the bath filled with Krebs solution saturated with 95 per cent oxygen and 5 per cent carbon dioxide. The temperature of the bathing solution was kept at 36° C. Isometric tension, produced by direct or indirect stimulation, was recorded with a mechano-electronic transducer (ROA 5734), and the membrane potential of diaphragm muscle fibres was measured with 3 M-KCl microelectrodes.

When  $[K]_o$  was low (0-2.4 mM), twitch tension of the diaphragm produced by direct or indirect stimulation was abolished or greatly reduced by adding insulin (0.1 to 1.1 i.u./ml.) in several min, and the contraction was restored in a few minutes when  $[K]_o$  was increased (4.8 to 6 mM), the findings of Offerijns *et al.* being thus confirmed. Intracellular recording of the membrane potential revealed that at the stage where the contraction was depressed by insulin, the resting potential of muscle fibres was markedly reduced (Table 1 and Fig. 1). At this time, the muscle action potential was greatly decreased

Fig. 1. Relation between resting potential and external potassium concentration in diaphragm muscle fibres of a potassium-deficient rat. Ordinate: O, membrane potential before insulin, and ●, after adding insulin 1.0 i.u./ml. Abscissa: potassium concentration in mM, on logarithmic scale. Potassium concentrations were changed by replacing equivalent amounts of sodium. Each point and vertical line represent a mean and  $\pm$  S.E.

in size, and in most fibres could not be produced by electrical stimulation. When  $[K]_o$  was increased to 5.9 mM, the resting potential was increased to more than 70 mV and the action potential of more than 100-mV amplitude could again be observed.

In the diaphragms from control rats fed on a normal potassium-containing diet, insulin neither influenced the muscle contraction nor produced the depolarization of muscle fibres at low  $[K]_o$ . The resting potential at which mechanical response disappears was determined by increasing  $[K]_o$  of the Krebs solution. The contractions to direct and indirect stimulations were abolished when the mean resting potential fell to 55 mV in 16 mM  $[K]_o$  from the original value of 71 mV in 4 mM  $[K]_o$ .

Fig. 1 shows the relation between the resting potential and  $[K]_o$  in muscle fibres of the diaphragm of a potassium-deficient rat. Insulin evidently exerted a depolarizing effect at low  $[K]_o$ . In 5.9 mM  $[K]_o$ , in contrast, insulin caused hyperpolarization. The latter fact is consistent with the previous findings in rat and frog muscles<sup>2,3</sup>. An explanation of the hyperpolarizing action of insulin might be the acceleration of electrogenic sodium extrusion<sup>4</sup>. However, the hyperpolarizing action was not abolished in the presence of ouabain,  $10^{-5}$  g/ml.

It is clear that the decline in resting potential following the application of insulin at low  $[K]_o$  is the main factor contributing to the failure of contraction. Further attempts were made to elucidate the mechanism of the depolarization by insulin. The depolarization is not dependent on the action of insulin to increase the glucose uptake of the muscle, because the depolarization by insulin, and consequently the decrease in the contractility, occurred in glucose-free Krebs solution. Similarly, the acceleration of active cation transport by insulin<sup>5</sup>, particularly the increased potassium influx<sup>6</sup>, cannot provide an explanation of the depolarization, because the depolarization occurred in the presence of ouabain  $10^{-5}$  g/ml, as well as in potassium-free solution. When sodium in the extracellular fluid was replaced by choline, the depolarizing action of insulin at low  $[K]_o$  was abolished (Table 1). The most plausible explanation of the depolarization by insulin, therefore, would be that insulin increases the permeability of the muscle membrane to sodium ions. Then the effects of  $[K]_o$  can be explained in the following way. A marked depolarizing action of insulin takes place at low  $[K]_o$ , where the permeability to potassium ions is reduced<sup>7</sup>. On the other hand, a rise of  $[K]_o$  restores the resting potential by increasing the potassium permeability<sup>8,9</sup>.

Table 1. DEPOLARIZATION OF DIAPHRAGM MUSCLE FIBRES OF POTASSIUM-DEFICIENT RATS IN VARIOUS EXPERIMENTAL CONDITIONS

Experimental conditions	$[K]_o$ (mM)	Concentration of insulin (i.u./ml.)	Resting potential* (mV)	
			Before insulin	After insulin
Krebs solution	1.2	0.14	70 $\pm$ 4	35 $\pm$ 2

## PHARMACOLOGY

### Transfer of Habituation by Material extracted from Brain

As an extension of our recent experiments on transfer of morphine tolerance<sup>1</sup>, we tried to explore the possibility of a similar transfer of the tolerance which develops to repeated physical stimuli. Such tolerance, called habituation, is defined as the loss of an innate response to a stimulus repeated without reinforcement<sup>2</sup>. It is considered to be one of the most elementary forms of learning.

The stimulus selected was sound which, when first heard, elicits a 'startle response' consisting of the contraction of various groups of skeletal muscles, accompanied by some autonomic changes<sup>3,4</sup>. The response is easily discernible even by untrained observers.

The sound was produced by a steel hammer hitting a metal plate. The hammer was connected to an electric timer so as to produce a sound every 5 sec. The loudness of the sound was 72 decibels at a distance of 1 m (with the reference pressure of  $2 \times 10^{-4}$   $\mu$ b) and its fundamental pitch was about 400 c/s.

Habituation was induced in rats (Sprague-Dawley strain, all males, weighing between 200 and 300 g) by submitting them to this stimulus for two 1-h periods daily. An additional 100 stimuli were given every day to follow the progress of the habituation. The test was recorded by an observer who pushed the button of an electric signal every time the animal failed to exhibit the startle response. This record was superimposed on the tracing made by the timer activating the hammer. Habituation was considered completed when the animals responded to 10 or less of the 100 stimuli applied on each of three consecutive days. Complete habituation was obtained in rats in  $9.0 \pm 4.5$  (S.D.) days. Mice lost their responses much more slowly; they failed to reach the criterion in 20 days.

The habituated rats were killed by bleeding. The brain was rapidly removed and frozen on dry ice. In the first series of experiments, a homogenate of pooled brains taken from sound-habituated rats was prepared and injected intraperitoneally to albino mice (Swiss strain, all males, weighing 20–30 g). A control group was injected at the same time with a similarly prepared homogenate of brain taken from normal, non-habituated rats. Prior to the injection, all the mice had been tested with 100 stimuli to ascertain that they responded normally to sound. About 16 h after the injection, the mice were tested again before being subjected to the two periods of stimulation. This schedule was followed every day until the end of the experiment. It should be noted that the observers who recorded the responses did not know to which group each mouse belonged.

Owing to the slowness of habituation in mice, the 10 per cent criterion was impracticable in these animals. The results of these experiments are expressed in terms of the mean number of days required to reduce to 50 per

Table 1. EFFECT OF DIFFERENT AMOUNTS OF VARIOUSLY PREPARED BRAIN EXTRACTS ON SOUND HABITUATION IN MICE

N, No. of mice in each group.

cent the responses of a group of mice. Table 1 lists the results obtained with different types of brain extracts and different amounts of brain administered.

It is seen that in the first experiments, using homogenates, there was a striking difference between the group which received the brain from sound-habituated rats and those which were given normal brain. However, homogenates are inconvenient to handle and to administer and they caused a high mortality in both the experimental and control groups. The first experiment lasted only six days.

Since the factor responsible for morphine tolerance was dialysable, we submitted the brain homogenates to dialysis against 20 vol. of distilled water at 4° C for 48 h. The volume of the dialysates was reduced by lyophilization and made up to contain the equivalent of 1 g of brain per ml. Two groups of mice were injected with these preparations: one with the dialysate of sound-habituated rat brain and the controls with normal rat brain. Table 1 shows essentially the same results as those obtained with the homogenates, but there were no deaths and the experiment was continued for 14 days.

Fig. 1 shows the habituation curve constructed with the pooled results of the first two experiments. The number of startle responses was spectacularly reduced in the experimental animals from the first post-injection test onwards. However, after the initial drop in the responses, the rate of habituation slowed down, suggesting that the effect of the treatment is of short duration. In some later

Fig. 1. Habituation curve of mice injected with extracts of normal rat brain (○) and brain from sound-habituated rats (●). Pooled data from the first two experiments shown in Table 1. Abscissa, days, starting from the day of injection; ordinate, mean number of startle responses to sound stimulus. Shading indicates the standard deviation of each mean value of 11 animals for days 1–6 and 4 animals for days 7–14.

experiments, a second injection given on the sixth day increased the habituation rate again.

Further purification of the transfer factor was done by treating the dialysate with 20 vol. of cold acetone. The precipitate was redissolved in water and injected into mice. Table 1 shows that this fraction was active when amounts equivalent to 140–340 mg of brain per mouse were given. The control preparation was inactive at 500 mg.

The transfer factor was found to be soluble in water, insoluble in acetone and 95 per cent ethanol. It is dialysable and, on partition with an equal volume of 88 per cent phenol, it goes into the phenol phase. These properties suggest that it is a peptide or small protein. This has been further confirmed by the disappearance of the activity when the preparation was incubated with crystalline chymotrypsin (1 mg/ml. at pH 8 for 1 h at room temperature). A similar incubation with pancreatic ribonuclease at pH 7 did not affect the activity.

Transfer of habituation has been described in *Planaria*<sup>4</sup>, but, to our knowledge, there is no reference in the literature to the possibility of transfer of any type of learning in higher invertebrates or in vertebrates. The results summarized here suggest that information is recorded and stored in the nervous system in terms of protein structure. Most chemical theories of learning and memory emphasize the role of RNA in information coding<sup>5</sup> and it is probable that persistence of the protein code requires some self-replicating mechanism, through the nucleic acids.

The preliminary experiments reported here show that an elementary form of learning, habituation to sound, can be transferred to untrained animals by injecting them with a peptide-type material extracted from the brain of habituated animals. This factor is absent from the brain of non-habituated animals. Further experiments are in progress in other learning situations, other routes of introduction of the transfer factor and with extracts of circumscribed areas of the brain.

### Effect of Calcium and Other Ions on Vasopressin Release from Rat Neurohypophyses Stimulated Electrically *in vitro*

THE rat posterior pituitary *in vitro* secretes vasopressin in response to a rise in extracellular potassium concentration. This effect of excess potassium is inhibited by magnesium and sodium ions and is strongly dependent on calcium. Secretion is abolished by omitting calcium from the incubation medium; it increases with increasing calcium concentration over a wide range, and is accompanied by uptake of calcium-45. From such evidence it has been concluded that calcium entry into the neurosecretory terminals on their depolarization by action potentials is the normal physiological event initiating secretion<sup>1-3</sup>. This concept is supported by the demonstration of vasopressin release from rat<sup>3,4</sup> and guinea-pig<sup>5</sup> neurohypophyses *in vitro* in response to electrical stimuli and of action potentials recorded from the supra-optico-hypophyseal tract<sup>6</sup>. It would clearly strengthen the hypothesis if it were shown that the effects of calcium and other

ions on vasopressin release, elicited by electrical stimulation, were similar to their effects on secretion elicited by excess potassium. This communication presents evidence that this is so.

In each experiment, neurohypophyses from five male Sprague-Dawley rats (200–350 g) were dissected out and incubated in bicarbonate Locke's solution at 37°C and stimulated at 40-min intervals for 5 min at a frequency of 20 shocks/sec using an adaptation of the procedure already described<sup>3</sup> that allowed the five glands to be stimulated simultaneously. Vasopressin released into the medium was assayed on the rat blood pressure.

In 53 experiments the mean 'resting' release of vasopressin between the 30th and 40th min after setting up the preparation was  $1.48 \pm 0.35$  (S.E.)  $\mu\mu/5$  glands/10 min. Electrical stimulation for the first 5 min of the succeeding 10-min period raised the mean output in this period to  $18.79 \pm 3.3$   $\mu\mu/5$  glands/10 min. This effect could be abolished reversibly by introducing 0.1 per cent procaine into the medium, and was therefore probably due to the production of electrical activity in the neurosecretory fibres.

The secretory response to electrical stimulation was completely abolished when the calcium concentration in the incubation medium was lowered to about 0.1 mM; it increased with increasing calcium concentration until this reached about 4 mM; and diminished as the calcium concentration was further raised to 8 or 16 mM. The curve relating vasopressin output in response to electrical stimulation to calcium concentration, obtained from experiments on 22 groups of glands, closely resembled that obtained previously using excess potassium to evoke secretion<sup>3</sup>.

An increase in the magnesium concentration of the medium from 1 to 10 mM approximately halved the output of vasopressin in response to electrical stimulation. This effect could be reversed by raising the calcium concentration of the medium ten-fold.

Reduction of the sodium chloride concentration of the medium from 160 to 10 mM (tonicity being maintained with sucrose) enhanced vasopressin output. Thus in five sets of glands stimulated in the low sodium medium vasopressin output was  $44.2 \pm 7.1$   $\mu\mu/5$  glands/10 min while the corresponding control values from the same sets of glands in the high sodium medium was  $22.5 \pm 1.7$ .

The effects of calcium, magnesium and sodium on vasopressin output in response to electrical stimulation thus closely parallel their effects on neurohypophyses stimulated with excess potassium<sup>1,3</sup>. The experiments thus lend further support to the hypothesis that the sequence of events involved in stimulus-secretion coupling in the neurosecretory terminals of the hypothalamo-hypophyseal tract may be: the arrival of impulses, depolarization, and the entry of calcium ions.

### Acute Toxicity of Extracts of Morning-glory Seeds in Mice

THE presence of alkaloids derived from lysergic acid in the seeds of the morning-glory varieties *Ipomoea violacea* (L.) and *Rivea corymbosa* (L.) Hall f. was discovered by Hofmann<sup>1</sup> and confirmed by several workers<sup>2-4</sup>. Reports of alteration of mental state after ingestion of morning-glory seeds have been made to this Directorate and have

also appeared in the public press. Osmond<sup>6</sup> reported an abnormal mental state after ingestion of the seeds of *Rivea corymbosa*, but Kinross-Wright<sup>7</sup> was not able to induce any such changes in eight subjects. Cohen<sup>8</sup> reported that some individuals appear to have no reaction whatsoever while others may respond as to *d*-lysergic acid diethylamide (LSD). In this same communication, a case of suicide following a recrudescence psychic reaction to ingestion of morning-glory seeds was also reported.

Analysis of the alkaloids of *Ipomoea violacea* by Hofmann<sup>9</sup> showed the largest component to be *d*-lysergic acid amide. There were smaller quantities of *d*-iso-lysergic acid amide, chanoclavine, elymoclavine and ergometrine. Solms<sup>10</sup> and Hofmann<sup>9</sup> reported on psychopharmacological experiments with *d*-lysergic acid amide in man. They observed psychotomimetic activity and a marked sedative effect after doses of 0.5 to 1.0 mg. Yui and Takeo<sup>11</sup> found that elymoclavine caused excitation in mice. Since studies of the total alkaloidal fraction rather than the individual components of morning-glory seeds would appear to be more relevant to the possible toxic effects in man, the following experiment was undertaken.

The alkaloidal fractions were prepared as follows: The defatted, ground (40 mesh) and wetted (10 per cent ammonium hydroxide) seeds were exhaustively extracted with ethyl ether in 30-g lots. The ether was shaken with 0.1 N sulphuric acid, the aqueous phase made ammoniacal, extracted with chloroform, the chloroform evaporated and the residue dried *in vacuo*. In Table 1 are shown the three varieties of morning-glory which were chosen—one variety with high, one with medium and one with very low alkaloid content. The latter served as a control to observe the possible effects of material other than alkaloids.

Homogenous aqueous suspensions of the solid residues of the alkaloidal fractions were injected intraperitoneally into Swiss mice. Table 2 shows the quantities injected and the alkaloidal content, calculated as ergometrine. It also shows the  $LD_{50}$  for two of the varieties. These were calculated by the probit method of Bliss<sup>12</sup>.

About 3 min after injection of the 'Pearly Gates' fraction there occurred loss of motor co-ordination, coarse tremors of the entire body, ataxia, piloerection, ptosis, slight cyanosis and hypersensitivity to touch. At lethal doses there were generalized convulsions and respiratory arrest. Among the surviving animals periodic bouts of fighting behaviour occurred, but these were ineffectual because of the motor impairment. Motor co-ordination improved 3–5 hours after injection, during which time fighting behaviour became more frequent. Finally the mice went into a deep sleep from which they could be easily aroused. There were no delayed deaths. The general impression was of a state of central excitation over-

laid by severe motor dysfunction at sub-lethal doses. At lethal doses severe depression supervened with death due to respiratory arrest. Extracts of the seeds of the 'Wedding Bells' variety produced, the same symptoms, but the excitation component of the reaction was much more intense.

Injection of 125 mg/kg of the 'Scarlet O'Hara' fraction was followed by slight depression and ptosis. The depression became more profound during the following hour, after which recovery began. At 200 mg/kg the above symptoms were noted along with piloerection and forward position of the ears. All the mice appeared normal after 24 h, but there was one death at 200 mg/kg 4 days later.

For comparison, mice were injected intraperitoneally with LSD-25, 40 mg/kg. This produced coarse tremors of the head and neck, piloerection, loss of motor co-ordination and ataxia. These effects were similar to those produced by the morning-glory seed extracts but were much less intense.

We thank Dr. R. E. Schultes, Botanical Museum of Harvard University, for identifying the morning-glory seeds.

### Central Action of Intravenous Curare

THE use of muscle relaxants as an adjuvant for immobilization in experimental neurology is widely accepted as standard technique. These agents are used because, when given parenterally under the usual experimental conditions, they apparently have little or no effect on central nervous activity<sup>1–7</sup>. Since it is known that neuromuscular blocking agents (especially *d*-tubocurarine and gallamine triethiodide) can markedly alter central nervous system activity when applied directly to the brain (pertinent references reviewed by Winterstein<sup>8</sup>), failure to observe central nervous system effects following intravenous administration of these drugs has been attributed to the existence of a functional barrier interposed between the blood and the brain<sup>9</sup>. Notwithstanding, and in apparent contradiction to this general consensus, several workers have reported a marked and well-defined central action of curare when administered parenterally<sup>11–13</sup>.

Paton<sup>14</sup> has suggested that failure of the barrier mechanism might account for those instances in which significant activity occurs. In line with this suggestion, it has been reported that alteration in the selectiveness of the blood-brain barrier can occur as the result of certain experimental procedures<sup>15,17</sup>. However, Cohen<sup>8</sup> was unable to demonstrate the presence of parenterally administered curare in central nervous tissue following large intravenous doses, hypoxia, hypercarbia, hyperalkalemia, or shock.

As an alternative approach to the problem, a study of the effect of intravenously administered *d*-tubocurarine on

Table 1. ALKALOID CONTENT OF THE SEEDS OF THREE MORNING-GLORY VARIETIES

Species	Variety	Quantity of seeds processed (g)	Weight of residue of alkaloidal fraction (mg)	% Total alkaloids*
<i>Ipomoea violacea</i>	'Pearly Gates'	254	187	0.041
<i>Ipomoea violacea</i>	'Wedding Bells'	400	290	0.023
<i>Ipomoea Nil</i>	'Scarlet O'Hara'	193	50	0.002

the central nervous system of an animal in which the blood-brain barrier mechanism was naturally ineffective was felt to be of value. By such an approach, the role of the blood-brain barrier mechanism in the exclusion of curare from the brain might be better understood. The young chicken was selected as the experimental animal because: (1) it does not develop a functionally mature blood-brain barrier until two to three weeks after hatching<sup>11,12</sup>; (2) the electrical activity of the brain shows essentially adult characteristics prior to this time<sup>13-15</sup>.

The present observations initially were obtained from 20 Rhode Island Red chickens, including both sexes, aged 10 days post-hatch (average weight  $72 \pm 8.0$  g). The findings afterwards were confirmed in birds from new hatch to 14 days.

Spontaneous electrical potentials from the optic tectum (TSA) and cerebral hemispheres (hyperstriatal area, HS), the photic evoked electrical activity from the optic tectum (PER) and retina (ERG) were recorded differentially. The reference electrode was in the neck muscles near their occipital insertion. Use of the neck muscles permitted a reliable estimate of the duration of drug action, since the appearance of muscle spikes on the cathode ray-oscilloscope could be used as the end-point.

The electrocardiogram, body temperature, and blood pressure of the cannulated ischiadic artery, were monitored throughout the experiments. A complete description of the techniques used has been published elsewhere<sup>16</sup>.

The *d*-tubocurarine used was the clinical product (Upjohn). The solution, which contained 3.0 mg/ml., was injected intravenously into the ischiadic vein. The initial injection of curare was always administered when the animal first showed signs of recovering from the general anaesthesia (ether). Subsequent injections were given when muscle spikes appeared on the oscilloscope trace, and averaged one every  $45 \pm 10$  min for a period of 8–10 h per experiment. The dose used was 6 mg/kg/injection throughout; this is approximately ten times the amount required to produce total paralysis in the chick for 10 to 20 min<sup>17</sup>.

Buttle and Zaimis<sup>18</sup> observed an immediate flaccid paralysis in the White Leghorn chick following intravenous curare<sup>18</sup>. In contrast, the lightly anaesthetized Rhode Island Red chick showed, at the onset of injection of the initial dose, pronounced body movement. The reaction was characterized by flapping wings and a running motion of the legs. Muscular activity of a fasciculate nature was also evident in the neck and torso. The severity of the reaction was such as to require physical immobilization of the animal to prevent it freeing itself from the stereotaxic apparatus, or dislodging the arterial or venous cannula. The response endured for approximately 2 sec prior to the onset of the usual flaccid paralysis. Subsequent injections of curare failed to re-induce the reaction, even when recovery from the preceding dose had progressed to the stage where muscle spikes generated in the neck muscles appeared on the oscilloscope trace. The possibility that this reaction could be re-induced if the animal were allowed to recover completely from the preceding dose of curare was not tested.

To determine whether the excitation reflected an action of curare within the central nervous system, the sciatic nerve was sectioned prior to the initial injection in ten experiments. In each instance the limb peripheral to the section failed to participate in the body movement. In

four experiments the spinal cord was sectioned at the upper cervical level. This eliminated all body movement.

The effect of curare on the cardiovascular system was inconsistent. There was no effect on the electrocardiogram or on the heart rate; however, changes in blood pressure did occur. The direction of these changes depended on the level of pre-drug pressure. In the lightly anaesthetized chick, the blood pressure was low (80–90 mm mercury). When curare was administered at such time, a rise in pressure of 10–20 mm occurred. But if curare was given when the blood pressure was at a level normal for animals of the age examined (140–120 mm mercury) a fall in pressure resulted. In both instances the change was transient, and pressures returned to pre-drug levels within 1 min. The hypotensive effect usually could be avoided by slow injection of the drug.

Changes in the TSA, HS or ERG were not evident following any of the multiple injections (Fig. 1). However, the photic evoked response (PER) was altered consistently and significantly following the first injection of curare. Changes in the primary negative wave of the potential seldom were evident, but the secondary components of the potential were enhanced markedly both in amplitude and frequency (Fig. 1, PER). A further alteration of the PER was not induced by subsequent injections of curare, even when the frequency of injection was greater than once every 45 min or when an increased dose was given. In no instance did curare alone depress or inhibit the electrical parameters (cp. refs. 12, 14 and 15).

These results strongly indicate that parenterally administered curare is capable of acting upon the central nervous system of the young chicken. Presumably, this is because the incompletely developed blood-brain barrier mechanism fails to prevent the entrance of the drug into the nervous tissue.

That curare does not affect the activity of the central nervous system in the chick in a manner similar to that observed in the mammal<sup>12-15</sup> is of interest. If the action of curare on the mammalian brain is, as suggested by Purpera and Grundfest<sup>19</sup>, suppression of inhibitory mechanisms, followed by inhibition of excitatory mechanisms at higher doses, the present results might indicate that the inhibitory mechanism in the chick brain is not physiologically prominent, or that inhibitory connexions are confined only to those systems giving rise to evoked potentials. In either instance it appears that the excitatory mechanism in the chick is far less sensitive to curare than is that in the mammal.

Fig. 1. Effect of parenterally administered curare on the electrical activity recorded from the optic tectum, eye, and cortex of the young chicken

a, control; b, during and immediately following the intravenous infusion of *d*-tubocurarine. HS, hyperstriatum; TSA, tectal spontaneous activity; PER, response evoked in the tectum by photic stimulation of the retina; ERG, electroretinogram. Downward deflections reflect negativity at the critical electrodes

That component parts of the electrical activities recorded from the avian tectum do show different pharmacological sensitivities has been suggested before. For example, Scholes and Roberts<sup>24</sup> have shown that  $\gamma$ -amino butyric acid inhibits the evoked potential while having little or no effect on the ongoing spontaneous electrical potentials, while the opposite occurs with pentobarbital.

This work was supported in part by grant B-1615 from the U.S. National Institutes of Health, and by a grant from the National Association for Mental Health awarded to Dr. Eugene Roberts, chairman of this Department.

## HAEMATOLOGY

### Interaction between Human Serum Complement and Normal Human Red Cells at Low Ionic Strength

Rapp and Borsoe<sup>1</sup>, in their study of the effects of low ionic strength on immune haemolysis, using sheep cells and guinea-pig complement, found that the erythrocytes were haemolysed in the absence of antibody at extremely low ionic strength. The authors gave details for the preparation of a number of isotonic sucrose buffers of various ionic strengths, and the buffers used in this work were those described by those authors.

We found that when normal human red cells were suspended in veronal sucrose buffer of low ionic strength ( $\mu = 0.009$ ) and mixed with fresh serum, diluted 1:20 in the same buffer, the red cells took up protein, most of which appeared to be C' protein. That these red cells absorbed C' protein was ascertained using the anti-globulin test and anti-C' antiglobulin reagent prepared as previously described<sup>2</sup>, which did not agglutinate normal red cells or red cells sensitized with various blood group antibodies but only after such sensitized cells had absorbed C' components.

In the experiments detailed in Table 1, all the sera or reagents were diluted 1:20 in veronal sucrose buffer, pH 7.4 ( $\mu = 0.009$ ). The red cells, obtained as citrated blood, were washed three times in normal saline and twice in the VB sucrose buffer and suspended in it to a strength of 10 per cent. Two volumes of the diluted reagent (Table 1)

Table 1. MAXIMUM AGGLOUTINATION = + + + + +

The reagents were diluted in veronal sucrose buffer, pH 7.4 (1:20), mixed with washed red cells (see text) suspended at 10 per cent in the buffer. Diluted reagent and red cells were mixed together for 0.5 h at 37° C, before the antiglobulin test.

Reagents	Antiglobulin test Anti-C'

R3	—
Serum heated 56° C, 5'	—
Serum absorbed AA/pt.	—
Fresh serum + NaHDTA	—
Fresh serum	+ + + + +

and one volume of the red cell suspension were incubated at 37° C for 0.5 h and then washed three times in normal saline before the antiglobulin test. The R reagents (except R11S, below) were made using standard methods and were tested using sensitized sheep cells; they showed no lysis but did show ability to re-combine.

Table 1 shows that R1, R2 and R4 failed to coat the red cells and gave a negative antiglobulin test, but mixtures of R1 and R2 and R1 and R4 did coat the cells and the antiglobulin test was positive. Heated serum, even when heated for only 5 min at 56° C, failed to coat the cells, as did serum absorbed with egg albumen-anti-egg albumen precipitate. Serum treated with EDTA and then diluted in veronal sucrose buffer and mixed with the red cells, as described above, also gave a negative result. These results suggest that the protein absorbed on to the red cell is complement protein.

The R3 reagent gave a positive result, but was only weakly positive. However, if 10 volumes of an appropriately diluted R3 reagent (1:20) were mixed with one volume of red cells, the result was strongly positive; other reagents, when mixed with the red cells, as previously described, continued to give negative results when used in the foregoing proportions, that is, 10 volumes of diluted reagent with 1 volume of cell suspension.

The R11S preparation was made by absorbing serum with aggregated  $\gamma_2$  globulin at pH 6.8, otherwise using the method of Muller-Eberhard and Kunkel<sup>3</sup>, as modified by Hinz and Mollner<sup>4</sup>. This reagent gave a negative result when tested under the conditions previously described, but a strong positive result occurred when the 11S material was added to the preparation; it is of interest to note that R1 + 11S gave negative results.

All these tests were done using group O red cells and mixed normal serum from healthy blood donors, but equally strongly positive results were given if red cells of groups A, B, or AB were mixed with fresh serum from an individual of the same ABO group. Experiments also showed that an individual's own red cells would give a positive result in the antiglobulin test under the conditions described when the individual's own fresh serum was used as a test serum.

When the tests, using fresh serum (as described above), were repeated using as a diluent a veronal sucrose buffer  $\mu = 0.037$  in place of the  $\mu = 0.009$  buffer, the result was either negative or only feebly positive (+).

It is of interest to note that the cells and serum can combine only at low ionic strength but, once the combination of certain C' proteins with red cells has occurred, washing in normal saline before the antiglobulin test, which was routinely carried out, did not affect the positive result; thus it is not necessary to maintain a low ionic strength once the union between C' and the red cells has gone beyond a certain stage.

Experiments have been carried out to try to determine whether there is a sensitizer present in normal serum, which must react with red cells prior to the action of C', but the results so far have been inconclusive and further experiments are in progress.

The above experiments suggest that under conditions of low ionic strength complement proteins are absorbed by normal red cells, but it is not known at the moment what these proteins are—nor is it known that all the proteins so absorbed are C' proteins. These results are of practical interest, as it may be possible to build up cells with a known complement constitution without having to use sensitized cells. Rapp and Borsos<sup>1</sup>, when referring to their work, wrote: "The discovery that erythrocytes can be lysed at low ionic strength by complement in the absence of added haemolysin, may have a bearing on the auto-immune phenomenon". The finding that human red cells can take up proteins from their own serum (which appears to be complement protein) adds interest to this suggestion, and it is hoped that the phenomenon will be of both theoretical and practical value.

*Note added in proof.* P. L. Mollison and M. J. Polley (*Nature*, 203, 535; 1964) have recently made similar observations.

### A Lymphocytosis-stimulating Substance in Mongoloid Plasma

RECENT investigations have again indicated that the thymus produces a hormone which stimulates the lymphoid tissues of the body<sup>1</sup>. In 1958, Metcalf indicated that the plasma of patients with lymphatic leukaemia contained a lymphocytosis-stimulating factor<sup>2</sup>. Metcalf's investigations on the extract from thymic tissue, as well as the work of other research workers, link the thymus with leukaemia<sup>3,4</sup>.

It is known that Mongoloids combine a high incidence of leukaemia with a chromosomal abnormality<sup>5</sup>. This observation suggested that Mongoloid plasma might contain a lymphocytosis-stimulating substance. This communication reports the results of an experiment to investigate this possibility.

Ten ml. of whole blood was obtained by venepuncture from five Mongoloids ranging from 10 to 20 years in age. The sodium salt of ethylenediamine tetraacetic acid was used as the anticoagulant. Control plasma was obtained from a healthy individual. Plasma was separated by centrifugation, placed in sterile tubes and frozen at -15° C until used. All the plasma samples were cultured on blood agar, brain heart infusion and thyol to check for contamination.

Each plasma sample was injected into 12-18 CFL strain of white Swiss mice which were 24-36 h old. Each animal was given 0.015 ml. intracerebrally on the parasagittal plane midway between the ears using a sterile 27 ga. needle and tuberculin syringe. Each day, starting 24 h after injection, blood from 2 mice from each plasma group was taken for total and differential white blood counts (WBC). Blood was obtained by severing the jugular vein with a sharp razor blade. Blood films were stained with Wright's stain. Counts were not continued beyond 9 days.

All five Mongoloid plasmas caused a lymphocytosis. The lymphocytosis reached its maximum on the fourth or fifth day, after which it decreased to a stable plateau. In the control animals, the lymphocyte count changed very little or dropped slightly. This time-treatment interaction was statistically significant (Fig. 1).

The treatment with Mongoloid plasma resulted in a mean of 49.2 per cent lymphocytes (high, 86 per cent;

Fig. 1. Comparison of the number of lymphocytes of mice injected with normal plasma, with the number of lymphocytes of mice injected with Mongoloid plasma. The number of lymphocytes is expressed as the log

low, 44 per cent); whereas the treatment with control plasma resulted in a mean of 39.5 per cent lymphocytes (high, 65 per cent; low, 36 per cent) over the 9-day period. This difference is statistically significant. These results are similar to those reported by Metcalf<sup>2</sup> with the exception that in this experiment the lymphocytosis reached its maximum level earlier.

Visual observations, as well as the weights of some animals, revealed that the mice injected with Mongoloid plasmas were smaller and weighed less, on any given day, than comparable controls. Since care and housing were the same for all animals, this difference could only be attributed to the treatment.

The differential smears revealed that the mice injected with plasma from a 12-year-old Mongoloid had an extremely high number of rubricytes. Relatively fewer rubricytes were present on all the other Mongoloid blood smears. On the control smears, rubricytes were seldom found.

We thank Dr. J. H. Gruter for his help with the blood counts, and Dr. W. G. Stover, superintendent, Apple Creek State Hospital, for his co-operation.

### Effects of Adenosine Diphosphate and Adrenaline on Mean Platelet Shape

If small particles are suspended in a fluid in which there is a velocity gradient, non-spherical particles will become orientated whereas spherical particles will not; this orientation alters the light transmission through a suspension of such particles. Thus the turbulence produced by shaking a test-tube containing a suspension of rod-shaped bacteria can be seen as a 'swirl' whereas a coccal suspension shows no 'swirl'.

Zucker and Zaccardi<sup>1</sup> have claimed that platelets change their shape and become more nearly spherical when exposed to adenosine diphosphate (ADP). This observation can be substantiated and studied in some detail by the following technique. Fresh heparinized or citrated platelet-rich human plasma is placed in a cuvette at 37° C

in an 'Eel' titrometer and stirred at about 500 r.p.m. by a captive magnet. The output, suitably magnified, from the photoelectric cell operates a pen recorder. The platelets are seen to swirl and this is recorded on the tracing as a rapid excursion of moderate amplitude while the mean optical density (*O.D.*) remains constant. Inspection of these platelets under the microscope shows considerable pleomorphism—disks and distorted elongated shapes with some pseudopodia and spicules. If 'Benadryl' or cocaine is added during stirring a drop in the mean *O.D.* occurs as a result of the dilution and then the amplitude of the tracing becomes gradually much smaller (Fig. 1, *BEN*). If the platelets are examined under the microscope at this time they are seen to have become spherical with no spicules. Thus a tracing of large amplitude indicates swirling and non-spherical platelets, and one of small amplitude indicates spherizing. If sufficient ADP is added to a sample of platelet-rich plasma to produce a small degree of aggregation, the mean level of the tracing goes down since the mean optical density decreases with aggregation. The amplitude decreases at exactly the same time as the mean *O.D.* begins to decrease.

Fig. 2 (*ADP*) suggests that the average platelet shape changes towards a more spherical form, and that this occurs simultaneously with the increase in stickiness which is reflected by the beginning of aggregation. As aggregation progresses the platelet masses increase to such a size that they then interfere with the light path and the amplitude of the tracing again increases. Thus a change in amplitude related to a change in shape is only evident before sizable aggregates are formed. If the stirring is continued the platelets disperse and the amplitude of the tracing usually becomes small again but does not revert to the pre-ADP level: this suggests that these dispersed platelets remain more spherical than they were initially. The addition of more ADP does not then alter the amplitude in spite of renewed ADP-induced stickiness and aggregation. Thrombin (Fig. 2, *TH*), 5-hydroxytryptamine, tri-ethyl tin and tendon extract (collagen) (Fig. 1, *COL*) all produce aggregation after a delay of 10–360 sec depending on which compound is used. In each case a decrease in amplitude occurs, not when the compound is added but at precisely the same time as the beginning of aggregation. It is probably relevant that all the foregoing compounds are thought to produce aggregation by causing

Fig. 1. *BEN*, 2 ml. platelet-rich plasma was stirred. The arrow indicates the addition of 0.2 ml. saline containing 2 mg. of 'Benadryl'. This tracing illustrates spherizing with no aggregation. *COL*, The arrow indicates the addition of 0.1 ml. of a saline suspension of homogenized human tendon.

Fig. 2. Experiments and recording similar to Fig. 1. The additions were: *ADP*: 0.1 ml. of saline containing 0.5  $\mu$ g. of adenosine diphosphate. *TH*: 0.1 ml. of saline containing 0.0025 units of human thrombin. This tracing and that of *ADP* and *COL* illustrate the 'rounding up' of platelets at the same time as aggregation begins. *AD*: 0.1 ml. of saline containing 0.11  $\mu$ g. of adrenaline acid tartrate. This tracing illustrates aggregation in the absence of a change in platelet shape.

the liberation of intrinsic platelet ADP. As reported<sup>1</sup>, adenosine added before the ADP prevents both aggregation and change in shape. With the present method no change in amplitude or *O.D.* occurs in such an experiment. Concentrations of ADP too weak to cause aggregation do not cause a decrease in amplitude. Platelets collected into EDTA are not sticky and they regularly give a tracing of small amplitude.

There are many differences between the response of platelets to adrenaline and to ADP<sup>2</sup>. Fig. 2 (*AD*) shows that the addition of adrenaline does not produce a change in the amplitude, and visible swirling in the cuvette persists even though aggregation occurs. Later the amplitude increases as large aggregates form. It seems therefore that no change in shape occurs despite an increased stickiness and aggregation.

Platelets in the early stages of aggregation were fixed in glutaraldehyde and examined under the microscope. The differences observed were not clear-cut, but in general platelets before the addition of an aggregating agent tended to be oval and flattened with a smooth outline. The addition of adrenaline in small concentrations did not materially alter their shape whereas after the addition of ADP the platelets were more rounded, with some spicules. It seems likely that the amplitude of these tracings in the first few seconds and the presence or absence of visible 'swirl' are influenced by the mean platelet shape, although other factors may contribute. When ADP is added the average platelet shape changes simultaneously with the development of stickiness, and the platelets remain more rounded after they have dispersed. This change in shape is probably related to the onset of stickiness even though it persists after dispersion. Conversely, it seems probable that no change in mean platelet shape occurs when platelets become sticky under the influence of adrenaline. These observations may suggest that the adhesive forces in these two situations are different.

This work was carried out during the tenure of grants from the Medical Research Council and the British Heart Foundation.

## HISTOLOGY

## Use of Inhibitors in Cholinesterase Histochemistry

PRESENT-DAY histochemical methods for demonstrating cholinesterases require the use of inhibitors in order to distinguish between acetyl- (that is, true, or specific) cholinesterase (AChE) and butyryl- (non-specific) cholinesterase (ChE). The histochemical technique determines AChE and ChE together, so that if either enzyme is inhibited without the other being affected, only the latter can be determined; thus an inhibitor of ChE makes it possible to determine AChE and vice versa.

Holmstedt<sup>1</sup> strongly recommends the use of 'Mipafox' as a selective inhibitor of ChE and of 'BW284c51' as a selective inhibitor of AChE. Pearse<sup>2</sup> recommends 'iso-Ompa' (DPDA) and 'BW62c47', respectively, because of the greater distance between the concentrations that cause 50 per cent inhibition (most readily expressed as pI 50, the negative logarithm of molar concentration of the inhibitor producing 50 per cent inhibition of the enzyme). Later, Holmstedt and Sjöqvist<sup>3</sup> stated that the selectivity depends not only on the distance between the pI-50 values, but also on the slope of the inhibition curves for the two enzymes. Holmstedt<sup>1</sup> published inhibition curves determined under histochemical conditions for the inhibitors 'DFP', 'Mipafox', 'BW284c51', '302IS' and '306IS'. Curves for 'iso-Ompa', 'BW62c47' and 'Lysivane', a useful inhibitor according to Pearse<sup>2</sup>, have not been published.

We determined inhibition curves for 'iso-Ompa', 'BW62c47' and 'Lysivane' titrimetrically at pH 8 with acetylcholine chloride as a substrate. Although our curves were not determined under histochemical conditions as were Holmstedt's, they are nevertheless an indication of the usefulness of the inhibitors (see Figs. 1-3). It must be mentioned, however, that the degree of inhibition is reduced by decreasing the pH (Heilbronn<sup>4</sup>).

The AChE inhibitors 'BW284c51' and 'BW62c47' show but little difference in the slope of their curves and in their pI-50 distances. As the curves of Holmstedt (for 'BW284c51') were determined under histochemical conditions while ours (for 'BW62c47') were not, there is no reason to reject 'BW284c51' as the preferable inhibitor. According to Holmstedt<sup>1</sup> a useful concentration for 'BW284c51' is  $5 \times 10^{-6}$  M.

Of the ChE inhibitors 'iso-Ompa', 'Mipafox' and 'Lysivane', the last is useless as a histochemical agent because of the slope of its inhibition curve for AChE, even though its pI 50-values for AChE and ChE are quite well separated. Both 'iso-Ompa' and 'Mipafox' are well suited, but both show a marked difference in inhibitory power for different animal species<sup>5,6</sup>. Which inhibitor should be used

Fig. 1

Fig. 2

Fig. 3

depends on the species under examination. When no curves of the inhibitor's effect on the enzyme of a certain species are known and where it is difficult to determine them, 'Mipafox' and 'iso-Ompa' may both be used, though in separate experiments. Holmstedt recommends a concentration of  $4 \times 10^{-6}$  M for 'Mipafox'; 'iso-Ompa' can be used at concentrations of from  $3 \times 10^{-5}$  to  $10^{-4}$ .

For AChE we used a purified product from the electric eel (Sigma, St. Louis, U.S.A.), except in our examination of 'iso-Ompa', where fish brain homogenate (three-spined stickleback) was used. For ChE we used a serum fraction from human serum kindly supplied by the Netherlands Blood Transfusion Service, Amsterdam.

'Iso-Ompa' (DPDA, tetra-isopropyl-pyrophosphoramidate) was obtained from Light and Co., England; 'BW-62c47h' (1,5-bis-(trimethylammoniumphenyl)-pentane-3-one-di-iodide) was a gift from the Wellcome Research Laboratories, Beckenham, England; 'Lysivane' (profenamine, diethylamino-2-propyl-10-phenothiazine) was a gift from Specia, Paris.

# PATHOLOGY

## Growth of Mammary Tumours in $F_1$ Hybrids

TRANSPLANTS from inbred strains to  $F_1$  hybrids derived from one isologous and one foreign parent are generally regarded as compatible. Skin grafts are accepted under these conditions, and most tumours give 100 per cent takes when transplanted by fragments or by inoculation of a heavy suspension. However, Snell<sup>1</sup> reported decreased incidence of takes in  $F_1$  hybrids when small inocula were used, and recently Hellström<sup>2</sup> has described similar findings using induced fibrosarcomas and a spontaneous mammary carcinoma. These reports raise the question whether all tumours exhibit this effect when transplanted in low dosage from their strain of origin to  $F_1$  hybrids.

This prompted the analysis of some previously unpublished work carried out in the Department of Pathology, University of Manitoba. At this time,  $C3H/HeJ$  mice were in very short supply, and  $F_1$  hybrids were produced by mating male  $C3H/HeJ$  and female  $C57L/J$  mice. The experiments were performed originally as part of an investigation of the effect of irradiated cells on transplantation of small numbers of viable cells<sup>3</sup>.

All the mice used for breeding were obtained from the Roscoe B. Jackson Laboratory, Bar Harbor, Maine. The two strains used differ at both  $H_1$  and  $H_2$  histocompatibility loci,  $C3H/HeJ$  having  $a$  and  $b$  alleles and  $C57L/J$  having  $c$  and  $b$  (ref. 4). Only one litter of  $F_1$  hybrids was used from each female. Mice were weaned at 4 weeks and used as tumour hosts at 10 weeks.

Two tumours were used, the  $C3HBA$ , which is a long transplanted and widely used mammary adenocarcinoma, and tumour  $D$ , a mammary carcinoma arising in an aged  $C3H/HeJ$  female, and in its tenth transplant generation in the laboratory at the time of use. Neither tumour had been carried in  $F_1$  hybrids before the experiments. Tumour cell suspensions were prepared by slow stirring of minced tumour in Earle's solution containing a weak concentration of trypsin. Counted numbers of tumour cells (unstained by nigrosin) were injected in 0.1 ml. of volume, intramuscularly into all four legs. All animals were kept under observation until death, or for at least six months. Low doses of inocula were given alone and also mixed with heavily irradiated cells. The latter had received 12,000 r. X-irradiation and never gave rise to tumours by themselves. Results are listed in Table 1 and shown in Figs. 1 and 2 for the  $C3HBA$  tumour, and in Table 2 for tumour  $D$ . Since each animal received four inocula, results show total number of takes and number of animals dying with tumours. Figs. 1 and 2 are survival curves and do not record individual takes.

Table 1. GROWTH OF  $C3HBA$  TUMOUR IN  $C3H/HeJ$  AND  $C3H/HeJ \times C57L/J$  HYBRIDS

Inoculum	Host	No. of takes	No. of animals dying with tumour	Average survival in days*
$10^4$ viable cells	$C3H/HeJ$	55/60	15/15	$33.8 \pm 10.1$
$10^4$ viable cells	$C3H/HeJ \times C57L/J$	59/60	15/15	$33.6 \pm 5.5$
50 viable cells	$C3H/HeJ$	0/40	0/10	—
50 viable cells	$C3H/HeJ \times C57L/J$	0/40	0/10	—
50 viable +	$C3H/HeJ$	23/58†	13/15	$56.2 \pm 14.3$
$10^4$ irradiated cells	$C3H/HeJ \times C57L/J$	35/58†	14/15	$55.0 \pm 11.2$

\* Survival of animals with tumours,  $\pm$  standard deviation.  
† One animal in each group received 2 inocula only.

Table 2. GROWTH OF TUMOUR  $D$  IN  $C3H/HeJ$  AND  $C3H/HeJ \times C57L/J$  HYBRIDS

Inoculum	Host	No. of takes	No. of animals dying with tumour	Average survival in days*
$1.5 \times 10^4$ viable cells	$C3H/HeJ$	24/32	7/8	$88.1 \pm 6.1$
$1.5 \times 10^4$ viable cells	$C3H/HeJ \times C57L/J$	20/40	8/10	$103.6 \pm 17.2$
250 viable cells	$C3H/HeJ$	0/40	0/10	—
250 viable cells	$C3H/HeJ \times C57L/J$	0/40	0/10	—
250 viable +	$C3H/HeJ$	23/40	10/10	$101.1 \pm 14.0$
$1.5 \times 10^4$ irradiated cells	$C3H/HeJ \times C57L/J$	23/40	8/10	$115.2 \pm 20.1$

\* Survival of animals with tumour  $\pm$  standard deviation.

Fig. 1. Survival curve of  $C3H/HeJ$  and  $C3H/HeJ \times C57L/J$  mice following inoculation of  $C3HBA$  tumour,  $10^4$  viable cells into each leg

Fig. 2. Survival curves of  $C3H/HeJ$  and  $C3H/HeJ \times C57L/J$  mice following inoculation of  $C3HBA$  tumour, 50 viable +  $10^4$  irradiated cells into each leg

It is seen that the incidence of successful takes is essentially the same with both tumours and at low and high dose ranges. Even the 'high' dose ranges would fall into the category of medium or low doses according to the previously mentioned investigations. None of the groups shows significant differences as to number of takes, number of animals dying with tumour, or average survival time of tumour-bearing animals. Figs. 1 and 2 show the close similarity between the  $C3H$  and  $F_1$  results using the  $C3HBA$  tumour. Tumour  $D$  gave similarly close results in an additional examination using intravenous inocula of  $10^4$  and  $10^5$  cells.

If an immunological factor were involved in the reduced growth in  $F_1$  hybrids found by other workers, one would expect that the presence of large numbers of irradiated cells might reduce the number of takes<sup>4</sup>. However, the results of Snell and of Hellström suggest that the reduced number of takes was not determined by immunological differences. The present results are not necessarily in conflict with those previously obtained, but they do suggest that reduced frequency of takes is not invariable in  $F_1$  hybrids even when very low doses of viable cells are used.

### Effect of Histidine on the Urinary Excretion of 4-Aminimidazole-5-carboxamide

We have recently shown<sup>1</sup> that patients with folic acid and/or vitamin B<sub>12</sub> (FA-B<sub>12</sub>) deficiency have an increased excretion of 4-aminimidazole-5-carboxamide (AIC) compared with anaemic patients who are not so deficient, or with non-anaemic hospital patients. A FIGLU test, using an oral load of 15 g L-histidine hydrochloride, was performed on many of these patients as a diagnostic procedure; since a haematological response has been observed in such patients following histidine dosage<sup>2,3</sup>, which would imply a partial correction at least of the disordered nucleoprotein metabolism present in these deficiencies, we have taken the opportunity to investigate its effect on the urinary excretion of AIC, itself an intermediary in purine synthesis. For this purpose urine passed between 4 and 8 h after histidine dosage was examined (Period 3); urines collected during one hour in the morning immediately before the test (Period 2) and in some cases for a similar 5-h period the previous afternoon (Period 1) served as controls. For comparison, similar collections were made from 8 normal adult volunteers and 3 patients who had anaemia not associated with FA-B<sub>12</sub> deficiency. No dietary restrictions were imposed during the test. Urines were preserved with 1 ml. 6 N HCl per h of the save and stored at 4° C. AIC was determined by an ion-exchange chromatographic technique<sup>4</sup>. In order to minimize any errors in the timing of the urine collections all results were expressed as AIC µg/mg creatinine.

Table 1 shows the mean AIC excretion in the two groups. In the 11 subjects without FA-B<sub>12</sub> deficiency the excretion was significantly less in Period 2 than in either Periods 1 or 3 ( $P < 0.01$  in each case), but Periods 1 and 3 did not differ significantly. We therefore conclude that histidine does not normally affect AIC excretion and regard the low values in Period 2 as resulting from the diurnal variation reported elsewhere<sup>4</sup>. In the 11 patients with FA-B<sub>12</sub> deficiency where excretion in all three periods was measured, no statistically significant difference in excretion was found between these periods. In these subjects, however, values were slightly lower rather than higher in Period 3 as compared to Period 2. Inclusion of an additional number of subjects from whom urine was collected only over Periods 2 and 3 raised the total to 26, and the fall in AIC excretion during Period 3 was shown to be significant at the 2 per cent level. We therefore provisionally conclude that histidine does produce a fall in AIC excretion in subjects with FA-B<sub>12</sub> deficiency. However, the study of larger and more sharply defined subgroups within this broad classification would be desirable, as would further information on diurnal variations in the excretion of AIC and creatinine.

All the above subjects with FA-B<sub>12</sub> deficiency showed, by virtue of an increased excretion of formiminoglutamic acid and/or urocanic acid following histidine, evidence of a defect in the metabolism of C<sub>1</sub> units. It is difficult to visualize any role for AIC in purine synthesis in man which does not involve C<sub>1</sub> units, and we consider that this metabolic defect must account at least in part for the high excretion of AIC in such subjects, reported previously<sup>1</sup>. The provision of an increased number of potential C<sub>1</sub> units in the form of histidine might well, as a mass action effect, promote a more efficient utilization of AIC, accompanied by a decrease in its excretion. The resulting increase in purine synthesis might provide a basis for

explaining the haematological response noted in megaloblastic anaemia following histidine dosage.

If the high rate of excretion of AIC in anaemia is regarded as due to an impairment in the formylation of AIC ribotide in the absence of adequate quantities of folic acid, as occurs in sulphonamide inhibited micro-organisms, our experimental findings would all appear to be adequately accommodated. If this were the only abnormality, however, an overall depression of purine synthesis would be implied, whereas the exact opposite appears to be the case as judged from recent studies. The finding that patients with vitamin B<sub>12</sub> deficiency, for example, excrete a smaller than normal percentage of orally administered AIC has led to the suggestion that interference with feedback control of purine synthesis may mean that the shunt mechanism of by-passing nucleic acids in purine biosynthesis is functioning at a rate well above normal in these subjects<sup>5</sup>. Interpretation of AIC excretion is further complicated by the possibility that AIC might be a product of purine degradation. If such degradation were inhibited by histidine, as has been shown to occur in micro-organisms<sup>6</sup>, the effects of the latter on the haematological status and on the excretion of AIC could be explained.

### Lathyrism and 7,12-Dimethylbenzanthracene-Induced Carcinoma in the Rat

This lathyrin agent,  $\beta$ -amino-poprionitrile (BAPN), reduces the tensile strength of mesenchymal tissue and modifies the collagen content<sup>1,2</sup>. Since local tissue factors are believed to be of importance in tumour growth, BAPN was administered to rats in which tumours were induced by a polycyclic hydrocarbon. 7,12-Dimethylbenzanthracene (DMBA) was used because it regularly induces mammary carcinoma in young female Sprague-Dawley rats. The strain of rat, the age, and the hormonal status are important factors in the induction of mammary carcinoma<sup>3</sup>.

50-day-old female Sprague-Dawley rats were given a purified diet with or without addition of 0.5 per cent BAPN. 20 mg 7,12-dimethylbenzanthracene in sesame oil was administered intragastrically at the beginning of the experiment in a single dose<sup>4</sup>. The time of induction, rate of growth and number of tumours were noted for 150 days. Urine samples were collected at 60–70 days after the beginning of the experiment. Oestrogenic substance was extracted, chromatographed on a 3.5 per cent hydrated alumina, and measured by a micro-Kober reaction<sup>5,6</sup>.

The animals were divided into three groups: Group I, intact female rats; Group II, DMBA; Group III, DMBA and BAPN. The lathyrin rats (Group III) developed tumours at an earlier stage than the control rats (Group II). The tumours in the lathyrin group grew faster and the total weight of tumour mass was significantly greater than in the Group II rats. Lathyrin rats did not show any significant increase in the number of tumours. The results are summarized in Table 1.

Table 1. URINARY AIC EXCRETION  
(µg/mg creatinine; mean  $\pm$  S.E.)

	No. subjects tested	Pre-histidine	Period 2	Post-histidine
		Period 1 (afternoon)	(morning)	Period 3 (afternoon)
Normals and non-deficient anaemic patients	11	0.62 $\pm$ 0.029	0.50 $\pm$ 0.029	0.65 $\pm$ 0.029
Folic acid and/or vitamin-B <sub>12</sub> deficient patients	11	2.09 $\pm$ 0.120	1.84 $\pm$ 0.120	1.77 $\pm$ 0.120
	26	—	2.20 $\pm$ 0.164	1.59 $\pm$ 0.164

Table 1. INCIDENCE, INDUCTION TIME, AND WEIGHT OF TUMOURS IN RATS TREATED WITH DMBA AND BAPN

Group	No. rats	No. tumours	Mean tumour induction time (days $\pm$ S.D.)	Mean tumour weight (g $\pm$ S.D.)
I Control	12	0	(days $\pm$ S.D.)	(g $\pm$ S.D.)
II DMBA	12	2.5 $\pm$ 0.4	71.8 $\pm$ 30*	0.80 $\pm$ 0.81
III DMBA + BAPN	12	3.4 $\pm$ 0.4	53.9 $\pm$ 19	3.10 $\pm$ 0.26

\* Standard deviation of the mean.

The tumours were glandular carcinomata. The microscopic appearance did not differ significantly between groups. In all Group III rats there was objective evidence of lathyrium consisting of osteochondral and visceral defects.

It should be noted that these tumours did not metastasize to the internal mammary chain, nor to the lungs or pleura. Although the tensile strength of collagen tissue was reduced, the only change noted was an increase in the local size of the tumour mass. Lymph node hyperplasia in the regional area was a constant finding.

Oestrogen assay at 60 days indicates that DMBA lowers the oestrogen excretion of the rat. BAPN did not have any effect on oestrogen excretion, as noted in Table 2.

Table 2. OESTROGEN EXCRETION 60-70 DAYS AFTER DMBA ADMINISTRATION

Group	I	II	III
Oestrogenic substance ( $\mu$ g/day)	0.176	0.068	0.060

The present results support the contention that BAPN administration accelerates the process of tumour induction and growth<sup>7</sup>. It does not appear to change factors relating to metastatic spread. It also appears that a change in hormonal milieu is an associated factor in tumour induction. Huggins *et al.*<sup>8</sup>, Wong *et al.*<sup>9</sup> and others have reported that adrenal necrosis and lower corticosterone levels follow DMBA administration. Oestrogen excretion may also be lowered.

In summary, lathyrium accelerates the induction and growth of mammary tumours in rats given DMBA. It does not change the microscopic appearance of tumour tissue. DMBA lowers oestrogen secretion.

BAPN fumarate was obtained as a gift from Dr. D. V. Frost, Abbott Laboratories, North Chicago, Illinois.

### Elastolysis and Giant Cell Reaction against Disintegrated Elastic Fibres

Of the vascular diseases in the surgical field, pulseless disease<sup>1</sup> and giant cell arteritis<sup>2</sup> are histologically characterized by the presence of a granulomatous inflammation as well as elasticophagic giant cells.

Degenerating elastic fibres have been implicated as the cause of granulomatous tissue reaction with formation of giant cells<sup>3</sup>. Since the demonstration by Baló and Banga<sup>4</sup>

that pancreatic extract contains an enzyme (elastase) which dissolves elastic fibres, a considerable number of reports have been published on the elastolytic process by the action of elastase<sup>5</sup> and the production of elasticophagic giant cells *in vitro*<sup>6</sup>, but little is known about the relationship between elastase and elastic tissue *in vivo*, and it remains to be determined whether an intense giant cell reaction is provoked by a primary degeneration of elastic tissue or a secondary elastic injury due to various causes.

The present experiments were carried out to determine whether a cause-and-effect relationship exists between degenerating elastic fibres and granulomatous tissue reaction accompanying giant cell formation *in vivo*. Rabbits weighing 2,000-3,000 g were used.

In order to destroy elastic fibres of the vessel wall, an elastase suspension (0.3, 0.5 and 1 per cent, N.B.C. and Sigma Company) with 0.2 M borate buffer at pH 9.0 was administered to the common carotid arteries of the animals by intravascular infusion under firmly applied ligatures (A) or periadventitial injection (B).

Also an attempt was made to activate the reticulo-endothelial system by typhoid-paratyphoid vaccine which was initially administered intraperitoneally, at a dosage of 3 ml. per kg, and a few days later 0.5 ml. in the neck.

**Experiment A.** After submitting the vessels to the action of elastase for 20 min to 7 days before the ligatures were withdrawn, the segments of the vessels were removed at intervals ranging from 2 to 90 days. Although no noticeable degradation of elastic fibres was seen during the first 20 min attack by elastase, remarkable elastolysis was recognized after 40 min.

One week after the injury there was a concentric or eccentric thickening in the intima, usually depending on whether the whole circumference of the media or only part of it was affected, composed of increased metachromatic material, fibroblasts and newly formed reticular and elastic fibres, and after 2 weeks smooth muscle cells were present.

Multinucleate giant cells phagocytosing the fragments of disintegrated internal elastic lamina were recognized (Figs. 1 and 2). Fibrinoid degeneration was occasionally observed. The media showed disintegrated elastic fibres and a decrease of the metachromatic material. In the adventitia, a proliferation of fibroblasts and mononuclear cells was noticed. There was no elasticophagic giant cell reaction in cases which were suffering a very severe disintegration of elastic fibres. In the cases without injection of the vaccine, there was no giant cell reaction and no noticeable inflammatory cell infiltration.

**Experiment B.** Neither elasticophagic giant cell nor thrombus was present, although an intimal thickening as well as destruction of the media and adventitia were seen.

Fig. 1. Section of common carotid artery, fifteen days after submitting the vessel to the action of 0.3 per cent elastase suspension for 3 h. (Haematoxylin and eosin,  $\times$  402)

Fig. 2 Section of common carotid artery, twenty-one days after the same experiment as presented in Fig. 1. (Weigert's resorcin fuchsin and Van Gieson,  $\times 402$ )

From these results, it is clear that elastase has an elastolytic activity *in vivo* and the fragments of elastic fibres exist as foreign bodies, and it is reasonable to presume that the following conditions are necessary for the occurrence of elasticophagic giant cells: (1) a specific destruction of elastic fibres to provoke giant cells—for example, hard and slightly soluble fragments of internal elastic lamina; (2) a mesenchymal activation brought about by some factors.

## IMMUNOLOGY

### Anti-elastin Antibodies in Normal and Pathological Human Sera

SOLUBLE peptides obtained by alkaline-alcoholic degradation of bovine aorta-elastin were shown to be antigenic in rabbits<sup>1</sup>. Though these peptides (the so-called  $\alpha$ -elastin<sup>2</sup>) are of relatively low molecular weight, passive haemagglutination titres up to about 1/1000 could be obtained<sup>3</sup>.

Specific precipitation tests were then performed on normal and immunized rabbit sera, using <sup>125</sup>I-labelled  $\alpha$ -elastin<sup>4</sup>. These experiments showed that even normal rabbit serum precipitated with labelled elastin peptides if incubated for 1 week in the cold. The antibody titres were quite low, and only 1–2 per cent of the labelled peptides were present in the precipitate<sup>4</sup>. These results were similar to those obtained by Grabar for antigelatine antibodies<sup>5</sup>. The experiments were then extended to normal and pathological (atherosclerotic) human sera in order to explore a possible relationship between anti-elastin antibodies and pathological modification of the vessel wall.

Rabbit red cells were coated with  $\alpha$ -elastin prepared as described<sup>1,2</sup>, using tetrazotized benzidine as a coupler, and the passive haemagglutination test<sup>6</sup> performed with serial dilutions of decomplexed sera. Controls for agglutination of uncoated red cells and for self-agglutination were included in every run. We report here the

Fig. 1. Frequency distribution of anti-elastin titres in human sera

Fig. 2. Anti-elastin titres in 100 human sera as a function of age

results obtained on the first 200 sera examined. Fig. 1 shows the frequency-distribution curves of haemagglutination titres for 68 severe atheromatous patients and 134 miscellaneous sera ('normal' sera, or from patients without recognizable signs of atheromatosis). Though most of the sera studied showed a very low titre (1/2–1/16), about 15–20 per cent of the normal population exhibited significantly higher titres (1/32 to 1/512). In the atherosclerotic sera, the distribution frequency of the low titres was similar to that in the normal population, but titres higher than 1/32 were not encountered. Fig. 2 gives the age distribution of titres higher than 1/8 for the whole population studied. It can be seen that sera with titres higher than this arbitrarily chosen level belong to individuals between 20 and 70 years of age. Younger and older ones have titres between 1/2 and 1/8.

The specificity of anti-elastin antibodies was investigated by absorbing them to fibrous elastin (prepared by the alkaline extraction procedure<sup>1</sup> from bovine aorta), to insoluble collagen (bovine hide powder), or to bovine serum albumin (Armour). Twenty mg of each protein was added to 1 ml. of serum, incubated for 1 h at 37° C and overnight in the cold, then centrifuged. The supernate was tested for anti-elastin antibodies and the adsorption cycle repeated until constant titres were obtained. After 1–2 adsorptions of sera on fibrous elastin, the haemagglutination titre vanished (decreased to 1/2 or even below). Neither collagen nor BSA had any effect on the haemagglutination titres.

These results seem to indicate that anti-elastin antibodies are present in human sera. The low titres observed are probably due to the fact that only a fraction of the

peptides of  $\alpha$ -elastin carries the antigenic determinant. The absorption of these antibodies from the circulating blood to the elastic fibres in the vessel wall or elsewhere has also to be considered. We believe that desmosine and isodesmosine, the particular amino-acids involved in the cross-linking of elastin<sup>1</sup>, may play an important part as antigenic determinants<sup>1,2</sup>. If this is so, wide cross-reaction between elastins of different species (carrying these same amino-acids) could be expected.

It seems probable that the anti-elastin antibodies occurring in human sera can be considered as auto-antibodies. It can be hypothesized that cathepsin-like enzymes slowly degrade elastin<sup>3</sup> and release soluble peptides into the circulation. These peptides would elicit the antibody response. As elastin is an insoluble structural protein, its soluble derivatives might not be recognized as 'self' by the competent cells. These antibodies would have a tendency to react with elastic fibres, mainly at places where the degradative process renders them more accessible. An antigen-antibody complex could be formed by such a mechanism in the vessel wall. Such complexes may very well play a part in the formation or spreading of a local tissue lesion. One example of such a reaction is, for example, the immune nephritis<sup>4,5</sup>.

According to our hypothesis, the degradation of elastic tissue followed by antibody formation against the degradation products may be important in the pathological alteration of the vessel wall and especially in atheromatous plaque formation. This would explain the presence of anti-elastin antibodies in most of the human sera that were examined, as well as the absence of higher titres in the sera of severely atheromatous patients. In the latter, according to the hypothesis, the elimination of antibodies by adsorption to the eroded elastic structures would be more intensive than in normal individuals.

## Influencing the Survival of Skin Homografts by a Lymphatic Fistula

The lymphatic system plays an important part in a number of processes evoked by homografts. By an extirpation of the regional lymph nodes it is possible to prolong the survival of a skin graft<sup>1-3</sup>. A similar effect can be obtained by injuring the nodes by radioactive radiation or nitrogen mustard<sup>4,5</sup>.

The influence of the extirpation of nodes is of relatively short duration because further nodes are then linked with the lymphatics and take over the task of regional nodes<sup>6,7</sup>. We therefore tried to develop a lymphatic fistula in the regional lymphatic node and to evoke an interruption of the lymph system lasting for a longer period.

Table 1. INFLUENCE OF LYMPHATIC FISTULA ON SURVIVAL OF SKIN HOMO-GRAFTS

Skin graft only (days)	Drainage (days)	Air-pump drainage (days)	Air-pump drainage and irrigation (days)
14	13	17	27
16	16	52	19
12	23	23	34
16	13	23	51
10	12	20	35
12	51	70	18
	16	18	23
	23	23	19
	23	40	
		12	
Mean 13.1	21.0	30.7	28.2

Chinchilla rabbits weighing 2,500–3,000 g were used. Full-thickness skin grafts were transplanted from black donors to the ear of the Chinchilla recipients which were of different colour. Fistulae were developed in such a way that half the regional lymphatic node was extirpated after ligation of the blood supply and with a patent afferent lymphatic vessel; a drain of an inner diameter of 7 mm was sutured to the area which was thus created.

The first group consisted of control animals without drainage of the lymph system. In the second group we left only animals with drainage. In the third group we connected the drainage to an air-pump of a constant pressure of  $-0.2$  kp/cm<sup>2</sup>. In the fourth group we irrigated the injured surface of the node with a physiological solution containing heparin. After seven days the fistula was removed.

During the experiments all rabbits were kept in a special harness and injections of 'Heparin Retard Spofa' in doses of 4,000 units were administered subcutaneously twice daily.

Table 1 shows the results of the experiments. In the control group skin homografts on the ear of the rabbit survived an average of 13.1 days (10–16 days) until complete necrosis. In the second group the survival was 21.0 days on average (13–51 days). In the third and fourth groups the survival was practically the same, averaging 30.7 days (12–70 days) without irrigation and 28.2 days (18–51 days) with irrigation.

The results show that a long-term fistula with the possibility of lymph flow considerably prolongs the survival of grafts as compared with a control group as well as with a group without suction. We can therefore assume that in these two series the integrity of the lymph system is renewed much later as compared with experiments where only extirpation of the lymph nodes was performed.

## Chromosome Marker Studies in the Graft-versus-Host Reaction in the Chick Embryo

The production of splenomegaly and other lesions by the injection of adult avian blood into the chick embryo is due to an immunological reaction between donor blood cells and host embryo tissues<sup>1,2</sup>. Biggs and Payne<sup>3</sup> have shown that the reaction is accompanied by proliferation of donor cells within the host spleen. They were able to distinguish donor (male) cells from host (female) cells by

identifying the respective sex chromosome complements. Cells of male sex have a ZZ chromosome constitution, whereas female cells have a single Z chromosome<sup>4,5</sup>. The Z chromosome is the only large mediocentric element in avian cells and is therefore readily identified in good chromosome preparations. Thus Biggs and Payne demonstrated proliferation of donor (ZZ) cells in the spleens of female embryos injected with cockerel blood. However, they found that the majority of dividing cells were of host type and they suggested that increased proliferation of host as well as donor elements must be responsible for splenic enlargement. Their investigation was limited to an analysis of 170 cells sampled from 9 embryo spleens removed 4 days after injection. Despite the obvious desirability of obtaining further information regarding the relative roles of donor and host proliferation in producing splenomegaly, no subsequent work has been reported. It would appear that technical difficulties involved in the preparation of clear metaphase figures from avian tissues have prevented further application of the method to the identification of cells.

Recently a technique modelled on those at present applied in mammalian cytogenetics<sup>6</sup> has been used in this laboratory for the routine preparation of excellent metaphase figures of various organs of the chick embryo<sup>7</sup>. It has therefore been possible to make a more comprehensive study of the relative dynamics of host and donor proliferation within the embryo following the injection of blood, using the sex chromosomes as cell markers.

In the initial experiment eggs of hybrid White Leghorn  $\times$  Light Sussex lines of 13 days' incubation were injected intravenously with 0.1 ml. whole blood taken from a 12-week-old White Leghorn cockerel. In a second experiment eggs of known B blood group type were injected at the same incubation time with 0.1 ml. blood taken from a 6-week-old cockerel also of known B blood group. At daily intervals between 16 and 19 days incubation, groups of embryos were injected via the allantois with 0.1 ml. demecolcine solution (containing from 0.05 to 0.1 mg demecolcine according to the stage of incubation). Three hours later, embryos and their spleens were weighed, and spleens of female embryos were prepared for chromosome analysis as follows.

A disaggregated suspension of cells was obtained by gently 'kneading' the spleen in hypotonic solution (0.95 per cent sodium citrate). After standing for 20 min the suspension was centrifuged and the supernatant was replaced by fixative (3 parts ethanol: 1 part glacial acetic acid). After a further 30 min the cells were resuspended in an aqueous solution of 45 per cent acetic acid and a drop of the suspension was placed on a clean slide and 'air-dried' by warming gently over a low flame. The final stage of resuspension in aqueous solution is particularly important for the effective spreading of avian chromosomes by the 'air-drying' technique. Staining was carried out in lactic-acetic-orcein<sup>8</sup> and the preparations were viewed by phase-contrast microscopy.

In Table 1 means of spleen and whole body-weight are presented for the period under study. The marked rise in spleen weight following the injection of whole blood has been noted by a number of workers<sup>4,10</sup> and strongly contrasts with the small increase found in control embryos and in embryos injected with blood of the same B locus type. Table 2 shows the proportions of dividing cells of donor and host origin respectively in a number of female embryo spleens sampled at successive incubation periods. It is apparent, first, that donor cells form a progressively greater proportion as incubation proceeds. For example, after 16 days incubation (3 days after injection) up to 8 per cent of the dividing cells in spleens of female embryos are of male sex, but by 19 days incubation donor cells form up to 93 per cent of dividing cells, that is, the relative proportion of donor to host has been almost reversed. Secondly, no proliferation of donor cells occurs in spleens of embryos injected with blood of similar B group type.

Table 1

	19	101.5	28.0	100	80	80
	19	45.6	28.2	114	106	92.1
21/21 B Blood Group Donor ( $\delta$ ) to 21/21 B Blood Group Hosts ( $\phi$ )						
	18	13.8	22.9	100	0	0
	18	16.6	20.2	100	0	0
	18	84.7	21.7	100	69	69

Thus in a total count of 200 cells not a single donor cell was found 5 days after injection. On the other hand, when donor and host differed at the B locus 69 per cent of spleen cells were found to be donor in type. Thirdly, when a histocompatibility difference between donor and host exists, spleens of embryos of similar incubation contain similar proportions of donor cells, despite considerable variations in overall spleen weight. For example, after 19 days incubation, spleens of 23.0 mg, 45.6 mg and 155.8 mg contain 90, 92.1 and 84.9 per cent donor cells respectively. There was, in fact, a slight negative correlation between spleen size and percentage of donor cells at this period, but it did not reach a level of statistical significance.

It has previously been shown<sup>11</sup> that the amounts of RNA, DNA, and protein per g wet weight of spleen remain constant throughout the period of splenic enlargement, thereby suggesting that the increased spleen size is directly due to cellular proliferation. Although spleen size therefore gives some broad measure of total cell number, the proportions of donor and host cells blocked in mitosis by demecolcine treatment cannot provide an estimate of the relative numbers of cells of these types making up this total. Thus the proportion of cells of a given type arrested in metaphase during the three-hour period following demecolcine injection depends not only on the total number of such cells present, but also on the rapidity with which they are dividing. Obviously if donor cells are dividing more rapidly than host cells, then for a given number of both, donor metaphases will be found at a frequency exceeding that of the host by a factor dependent on the relative mitotic rates. Another consideration, albeit perhaps a minor one in view of the close correlation of DNA content to spleen size, is that selective destruction of host cells, which might occur in the later periods of

incubation and when the graft-versus-host reaction is intense, would accentuate the increase in relative proportion of donor cells.

Nevertheless, most of the increased spleen weight noted 8 days after the injection of blood must be attributed to host proliferation. At this stage the overwhelming proportion of dividing cells are of host type, although already, on average, spleen weight is increased by a factor of 2-3. The nature of the stimulus for host proliferation in the reaction is uncertain; that is, it may be secondary to the proliferative activity of donor cells or it may represent a concomitant host-versus-graft reaction, albeit occurring during embryogenesis when the host is generally regarded as having little or no immunological capacity.

It is equally clear that the rate of donor proliferation, between 3 and 6 days after injection, must considerably exceed that of the host. While donor cells form an increasingly greater proportion of dividing cells, mean spleen-weight continues to rise rapidly and it eventually exceeds that of the controls by a factor of 7. In these circumstances the possibility of host cell destruction merely underlines the intensity of donor cell proliferation.

It has been shown<sup>13</sup> that splenomegaly does not occur when donor and host are of similar B blood group genotype. The B blood group locus appears to be of major histocompatibility importance in the chick<sup>13</sup>, although other blood group loci may also be involved<sup>14</sup>. The results of this experiment show that when donor and host are of similar B blood group, no proliferation of donor cells occurs and in the absence of splenomegaly it must be presumed that no increased host proliferation occurs either.

The constancy in cell proportions found at any one incubation time, irrespective of spleen-weight, strongly suggests that both donor and host proliferation are interdependent. Thus although the overall rate of cell proliferation is related to the degree of histocompatibility difference between donor and host, the comparative proliferative rate of the two components is not related to histocompatibility but is the same for all embryos at any one time.

In summary it may be stated that, although it is clear that there are obvious difficulties in interpreting variations in the proportion of different cell types in terms of variations in actual number of cells, certain conclusions regarding the nature of the splenomegaly reaction in the avian embryo can be made. The initial increase in spleen weight is largely of host origin although when maximal weight increase is occurring, the rate of proliferation of donor cells exceeds that of host cells. The two rates bear a constant relationship to each other at all stages, host and donor cell proliferation being interdependent. Finally, no proliferation of donor cells occurs within the host spleen when donor and host are of the same B blood group type.

We thank E. M. McDermid, Thornber Bros., Ltd., Halifax, for supplying eggs of known B blood group.

## ANATOMY

### Isolated Rabbit Neurones: Electron Microscopical Observations

We have shown that neurones isolated in Ringer-Locke or in isotonic sucrose solutions lack the image of a surface membrane over the greater part of the soma and dendrites<sup>1</sup>. Since then, we have developed media in which an electron-dense surface image is maintained<sup>2</sup>. These investigations have been carried out on ox neurones, and while we have made efforts to isolate and fix the cells as soon as possible after the death of the animal, the time lapse involved is considerably longer than when smaller laboratory animals are used. Therefore we have made observations on rabbit neurones isolated by hand dissection and fixed at intervals between 12 and 60 min after the death of the animal. In addition, we have examined rabbit neurones which have been incubated for 2 h at 37° C in the succinoxidase assay mixture used in cytophysiological investigations of isolated nerve cells by Hyden *et al.*<sup>3,4</sup>.

Rabbits were given an air embolus and the carotid artery was severed as soon as they became unconscious. The brain was then rapidly removed, the lateral vestibular nuclei were excised and the neurones were dissected out free-hand in 0.25 M sucrose solution as described by Hyden<sup>5</sup>. Cells for immediate fixation were placed into 0.25 M sucrose solution in siliconized glass cavity slides, the sucrose solution was withdrawn and replaced by 1 per cent veronal buffered osmium tetroxide (pH 7.4) in which the cells were fixed for 30-60 min. The neurones were then prepared for electron microscopy as previously described<sup>1</sup>. Samples of neurones were also placed in siliconized glass cavity slides in which the sucrose solution was replaced by the succinoxidase assay mixture. These preparations were then enclosed in chambers by placing small 'Perspex' rings around the sample and sealing a piece of coverslip glass above. After incubating at 37° C for 2 h, the assay mixture was replaced by fixative solution and the cells were prepared for electron microscopy. Neurones were randomly selected for examination from a total of ten experiments.

As with ox neurones isolated in Ringer-Locke or 0.25 M sucrose solution, it was found that rabbit neurones fixed immediately on isolation lacked an electron micrographic image of a surface membrane over the greater part of the soma and dendrites. Fig. 1 shows part of a longitudinal section of a dendrite near its origin from the soma of a neurone hand-dissected from the lateral vestibular nucleus and fixed 12 min after the death of the rabbit. A surface membrane is lacking except for a small patch to be seen at the bottom left of the figure. Neurones incubated in the succinoxidase assay mixture also lacked a surface membrane over the major part of the soma and dendrites. Furthermore, these cells suffered greater disruption of their cytoplasmic structures than is usually observed in isolated neurones. In Fig. 2, which shows part of the soma of a cell incubated for 2 h in the assay mixture, the granular endoplasmic reticulum is very swollen.

It is clear that the rabbit neurones, when isolated from their supporting glia and stripped of many of their boutons, suffer a loss of the usual surface membrane image only minutes after removal from the brain and that this effect is strikingly similar to that seen in isolated ox neurones. It is clear from our investigations that the essential features of the physical boundary of isolated neurones is disrupted, thus the rates of transport of metabolites would be considerably altered from those occurring *in vivo*. Since some structural integrity would obviously be maintained, isolated neurones may reasonably be considered to be a 'partial homogenate'. It appears that metabolic examination of isolated neurones and glia should be monitored in order to establish the

Fig. 1. Longitudinal section of a dendrite of a neurone hand-dissected from the lateral vestibular nucleus of rabbit brain. Osmium tetroxide fixed 12 min after death of the animal

Fig. 2. Part of the soma of a cell similar to that shown in Fig. 1, but fixed after 2 h incubation in succinoxidase assay mixture

extent to which these systems reflect other essential features of the situation *in vivo*.

We thank Mr. David Gunn for assistance with photography.

**Note added in proof.** Since this communication was submitted for publication it has been reported that membrane potentials have been recorded from neurones hand-dissected from Deiter's nuclei of rabbits<sup>6</sup>. This observation is surprising in view of the findings described here. Further investigations are necessary both of the changes

in the surface following dissection and of the mechanism of the development of the recorded potentials.

## BIOLOGY

### Oscillation in the Simple Logistic Growth Model

THE logistic curve is often used in teaching ecology as a first description of growth of an animal population. For many reasons, frequency related to age structure and time-lag effects, it does not usually fit in practice; and a population may undergo oscillations of one type or another. The causes of oscillations have been discussed in detail by numerous authors (see refs. 1-5), some of whom propose more or less complex conditions which would generate them. Nevertheless, the logistic growth curve is a useful starting point in the study of population ecology, so that the following simple relation between the rate of increase, generation time and the type of approach to the 'saturation' level may be of interest.

If we assume that adult numbers in any generation are determined by the number of adults in the previous generation the type of approach can be predicted immediately from the intrinsic rate of increase ( $r$ ). The logistic equation can then be re-written:

$$N_{s+1} = N_s \cdot e^{r(1-N_s/K)}$$

where  $r$  is expressed per generation,  $K$  is the saturation density and  $N_{s+1}$  is the population size after one generation. Then, if  $\Delta N = N_{s+1} - N_s$ , we find  $d\Delta N/dN = (1 - Nr/K) \cdot e^{r(1-N/K)} - 1$ . From this equation it is seen that when  $N$  is equal to  $K$ ,  $d\Delta N/dN = -r$ .

The relation between  $\Delta N$  and  $N$  allows us to predict the type of approach to equilibrium that will occur<sup>6</sup>. In the present instance the population will (a) approach  $K$  gradually, provided  $r$  lies between 0 and 1, (b) undergo damped oscillations when  $r$  has values between 1 and 2, and (c) show oscillations increasing to the point of extinction when  $r > 2$ .

### Deposition of Human Polymorphonuclear Leucocytes on Glass

THE phagocytic activity of human polymorphs has been examined by depositing the cells on glass coverslips and observing their behaviour under phase contrast<sup>1</sup>. The coverslips were first prepared for use by boiling in distilled water followed by soaking in glass-distilled water for 3 h and then drying after washing in two changes of absolute alcohol, but it was found that cells collected from the buffy layer of human blood made up within 1 h of venepuncture adhered poorly to the surface of such cover-

slips. In contrast, the cells adhered well to the surface of glass coverslips which were used without any treatment other than rubbing with a paper tissue, though the numbers adhering were somewhat variable. As the principal difference between untreated coverslips and those which had been boiled in water and washed with alcohol was likely to be the existence of a layer of an oily substance at the glass surface, a defined layer of a fatty acid was deposited on the coverslips by a modification of the method of Blodgett<sup>1</sup>.

A glass dish, 20 cm in diameter and 5 cm deep, was filled with distilled water and 0.02 ml. of B.D.H. redistilled oleic acid was dropped on to the surface of the water. The bulk of the oil remained as discrete lenses and the rest spread as a monolayer due to the dipolar nature of the acid<sup>2</sup>. A coverslip, previously cleaned by boiling in water and drying in absolute alcohol, was held in a vertical plane and dipped in the water at a part remote from the oil lenses and the dipping was repeated five times so that a multi-molecular layer of oleic acid was deposited on the glass surface. The excess of water was allowed to drain and the coverslip was dried by standing vertically at room temperature.

A suspension of white blood cells was prepared by dispersing the buffy layer of blood in Medium 199<sup>4</sup>, and the polymorphs were deposited on coverslips within 1 cm × 1 cm areas, marked out by 'Speedry' marking ink (Speedry Products Ltd., Beckenham, Kent) by allowing 0.05 ml. of the suspension to sediment for 5 min in a moist chamber containing an atmosphere of 5 per cent carbon dioxide<sup>1</sup>. Microscopic counts with a calibrated eyepiece graticule showed that the number of polymorphs adhering to a series of multilayered coverslips was more than twice that adhering to a series of alcohol-treated coverslips, when the same cell suspension was deposited.

The oleic acid layer did not appear to affect the behaviour of the polymorphs. Using rice starch as a test particle, the average percentage phagocytosis (87) observed in a series of polymorph populations deposited on multilayered coverslips was no different from the average percentage phagocytosis (89) in a similar series of cells on alcohol-treated coverslips. Similarly, no significant difference was found between serum concentrations required to promote phagocytosis of hydrocarbon particles by 50 per cent of populations of polymorphs<sup>1</sup> deposited on either multilayered or alcohol-treated coverslips. The major difference between preparations deposited on coverslips multilayered with oleic acid and those deposited on alcohol-treated glass thus appeared to be the increased ability of the polymorphs to adhere to glass surfaces on which there had been deposited a layer of the fatty acid. This greater ability to stick made the scoring of quantal phagocytic responses much easier.

### Observation of Root Feeding by the Nematode *Trichodorus viruliferus* Hooper

OBSERVATION through the glass panels of an underground root observation laboratory<sup>1</sup> and subsequent sampling for detailed study have shown a high proportion of the white growing tips of extending apple tree roots to be attacked by the ectoparasitic nematode *Trichodorus viruliferus* Hooper. Colonies of 10 to more than 100 individuals congregated 1–3 mm behind the apical meristem of suitable roots (about 1 mm in diameter), rasping the epidermis and

hypodermis with their stylets and causing a superficial but characteristic browning. Severely damaged portions of the root often swelled and occasionally their surface split. Root extension usually ceased after 5–15 days of feeding, although the meristem itself was not the focus of attack. Once growth had ceased most of the nematodes dispersed within 1 or 2 days. The damage to the root tip was essentially the same as that associated with the 'stubby root' symptom in many herbaceous hosts, which has been ascribed to other species of this genus in the United States<sup>2</sup>. In extending apple roots, however, it was not accompanied by the characteristic branching and stopping of secondary and tertiary roots.

*T. viruliferus* comprised 95 per cent of the plant-parasitic nematodes recovered from the surface of roots withdrawn through removable panels, and rhizosphere soil from the same roots yielded 93 per cent, the remainder in each case consisting of *Paratylenchus* spp. Extending roots of the same trees, recovered by digging 2–4 ft. away from the trunk, yielded 85 per cent *T. viruliferus*, the remainder being *Paratylenchus* and *Tylenchorhynchus* spp. Soil sampled by auger from the same root zone and elutriated by conventional techniques yielded 7 per cent *Trichodorus* spp. and 81 per cent tylenchid genera (*Paratylenchus*, *Tylenchorhynchus* and *Pratylenchus* spp.). It appears, therefore, that *T. viruliferus* is concentrated on the surface (rhizoplane) and in the rhizosphere of roots to a far greater extent than the tylenchids, which form the majority of the soil population of root parasites. The detection of associations such as this would be difficult by the commonly used soil sampling and processing techniques, illustrating the potential of a root observation laboratory, with its facilities for direct observation and sampling and indirect study by means of time-lapse photography.

### Parasitism by Larvae of *Unionicola Intermedia* Koenike, and another *Unionicola* sp. (Acarina, Pionae), on Chironomids

THE majority of water-mites for which the life-histories are known have a parasitic larva and free-living nymphs and adults. The family Unionicolidae, however, has always been separated from the remaining families due to the fact that most species have adults and nymphs which are parasitic in the mantle cavities of fresh-water mussels. It has generally been assumed that these mussel parasites have been free-living as larvae and that the larval stage has been of brief duration and has served merely as a means of dispersal. There have, moreover, apparently been no previous records of these larvae being found outside their hosts.

During August and September of the past two years I have collected considerable numbers of the midge *Chironomus plumosus*, L., and on 64 out of 82 examined from three such collections I found 510 mite larvae referable to the genus *Unionicola*. These larvae have been identified as *U. intermedia*, Koenike, and probably *U. aculeata*, Koenike.

The former has been known since the time of Bonz (1783) as a parasite in its nymphal and adult stages of the mussel *Anodonta anatina*, L., while the latter is stated by Mitchell<sup>1</sup> to use mussels as sheltering places for its pupal stages but otherwise to be free-living.

It seems, therefore, that the larvae of these two members of the genus behave in a manner precisely similar to the

remainder of the super-family Pionae and that the parasitism of the adults can be looked on as merely an extension of the relationship mentioned by Mitchell for *U. aculeata*, Koen. This discovery, in fact, makes the whole position of the Unionicolidae much more readily acceptable, since it is no longer necessary to assume that they evolved differently from the remainder of the Pionae.

### Survival of *Fomes annosus* in Infected Roots in Soil

VARIOUS species of *Fomes* are known to cause considerable root damage to a variety of perennial crops including rubber and several conifer species. In most cases it has been shown that infected root tissue forms a significant source of inoculum for the infection of newly planted crops. Rishbeth<sup>1</sup> has given detailed descriptions of the field symptoms caused by *Fomes annosus* in the Breckland conifer plantations of East Anglia, pointing out that the disease usually appears in patches. By exposing root systems at different stages in the development of the disease, Rishbeth found that lateral spread within such a patch is primarily due to root contact, and that *Fomes annosus* has only a limited competitive saprophytic ability. The disease does, however, sometimes appear in areas not previously planted with conifers, and Rishbeth<sup>2</sup> later established that stump infections are of the greatest significance to the initiation of such new centres of infection.

From these observations it seems obviously desirable to have some measure of the survival capacity of *Fomes annosus* in soil, and to have some knowledge of the factors which might encourage a rapid disappearance of the fungus.

Initial experiments along these lines were based on artificially infected wood pieces, produced by culturing together the fungus and 1-in. lengths of pine stem of approximately  $\frac{1}{2}$  in. in diameter in a cornmeal sand mixture. After having been grown at laboratory room temperature for a period of six weeks, the wood pieces were removed from culture, washed briefly in tap water and buried in containers of Kettering loam soil<sup>3</sup>. Samples were removed from the soil at various intervals and planted on moist sterile sand in Petri dishes. After five days, observations under a binocular microscope showed the presence of the characteristic conidia of *Fomes annosus*. By assessing the degree of sporulation on an arbitrary scale of 0-4, an attempt was made to measure the period of survival of *Fomes* under these specific conditions.

The first experiment along these lines suggested that *Fomes annosus* disappeared from the buried wood pieces within four weeks of burial. However, the experiment was repeated with a three-months-old culture of inoculated wood pieces and, surprisingly, the fungus was replaced by a variety of soil saprophytes within one week of burial. This apparent contradiction did appear to be related to one obvious difference between the first and second experiments, namely, the appearance of the wood pieces before they were buried in soil.

The six-weeks-old inoculated wood pieces remained reasonably firm, with the bark securely in position, whereas after three months in laboratory culture conditions the bark had completely disintegrated on the inoculum used in the repeat experiment. By sectioning some of the original inoculum pieces it was later observed that the fungal invasion was limited to the outer layer of wood, and only penetrated more deeply when such wood pieces showed obvious fracture incurred during the cutting of the wood pieces.

With the knowledge that *Fomes* is known to survive for many years under field conditions, and the possibility that the presence of bark modified the results of the two previous experiments, the following experiment was set up with naturally infected wood pieces collected from newly killed specimens of *Pinus sylvestris* in the Breckland.

A bulk supply of naturally infected root tissue was collected from the Breckland. The trees selected for sampling were those in which the leaves were brown in colour but had remained attached, care being taken not to select those which *Polystichus abietinus* had invaded or those with very resinous roots. The roots were then sawn into 2-in. lengths (approx.) and classified as large, medium or small according to their diameter. Large ones were approximately  $1\frac{1}{2}$  in. diameter, medium ones 1-in. diameter and small ones  $\frac{1}{2}$ - $\frac{3}{4}$  in. diameter.

Twelve samples of wood from each category were then treated in each of the following ways: (a) the bark was removed and the cut end left uncovered; (b) the bark was maintained intact and the cut ends not covered; (c) the bark was left intact and the cut ends sealed with molten sealing-wax. Large boxes of Kettering loam soil were then prepared and all the wood pieces were buried to a depth of 4 in. These boxes were maintained in a heated greenhouse for a period of 18 months. During this time they were watered regularly as a routine operation. At the end of this period the soil surface was well colonized by a species of *Juncus* together with a series of annual weeds. The dominance of rushes was probably a reflection of the mildly acid soil conditions prevailing under these conditions<sup>4</sup>.

At the end of this burial period all wood samples were removed and thoroughly washed, and the degree of survival of *Fomes* was assessed by three different methods. The first consisted simply of splitting each root sample with a sterile scalpel and sub-culturing four wood chips from each sample in an acid 'Dox' medium. Within four days the presence or absence of *Fomes* was recorded for each isolation and the total number of positive records was calculated as an index of percentage survival. The second method consisted of wrapping the two wood segments, previously sub-cultured, in moist newspaper and incubating in a moist chamber for a period of seven days. At the end of this period examination of the wood pieces revealed the characteristic conidia of *Fomes* if the fungus was still viable. By recording the presence or absence of the fungus it was again possible to calculate percentage survival. The third method was simply to count the number of miniature brackets which were present on all wood pieces giving a positive record in either of the previous methods of assessment.

All the data collected in this manner are summarized in Table 1.

A simple examination of these data shows quite clearly that the presence of bark is a marked deterrent to the saprophytic colonization of the infected wood tissue and that the three methods of assessment give an extremely consistent pattern. It should be further noted that, whereas the plating index and the wrapping index give actual percentage survival in terms of the number of wood pieces showing the presence of the fungus, the fruiting index is probably a better index of the surviving inoculum potential.

Table 2 shows the effect of root diameter on the survival of *Fomes*, from which it is obvious that the larger samples survive more effectively than smaller samples, irrespective of the method of treatment. Garrett<sup>4</sup> has shown that the size of the nutritional substrate determines the inoculum

Table 1. SURVIVAL OF *Fomes annosus* IN SOIL AFTER BURIAL FOR 18 MONTHS

Treatment	Survival recorded by various assessment techniques		
	Plating index	Wrapping index	Fruiting index
Without bark	0	0	0
With bark	30	25	38
With bark and seal	85	58	91

Table 2. EFFECT OF SAMPLE SIZE ON SURVIVAL OF *Fomes annosus* AS RECORDED BY THE FRUITING INDEX

Sample size	Without bark	With bark	With bark and seal
Large 1½-in. diam.	0	31	70
Medium 1-in. diam.	0	6	21
Small ¾-in.-1-in. diam.	0	1	0

potential of *Armillaria mellea*. This concept was partially confirmed for *Fomes annosus* in the present series of experiments where the fruiting index for the larger samples far exceeds that for the smaller units.

The experiments reported here have shown quite clearly that the size of root sample, as well as the presence or absence of bark, plays a significant part in the survival of *Fomes annosus* in soil. Since the removal of infected root tissue is one of the methods used to control the spread of this parasite, this information is of considerable practical significance in that any method used which could lead to excessive damage to bark would be more conducive to the rapid disappearance of the parasite.

This work was carried out at the Botany School, University of Cambridge.

## Vitamin B<sub>12</sub> Analogues In Non-legume Root Nodules

It has been shown<sup>1-4</sup> that cobalt must be available for legume nodules to supply fixed nitrogen efficiently to the plant bearing them. It has also been shown that in such nodules cobalt is elaborated into the form of vitamin B<sub>12</sub> analogues. Thus Levin *et al.*<sup>5</sup>, using *Ochromonas* and *Eruglena* assays, reported that appreciable (though not actually stated) amounts of the vitamin were present in nodules of lucerne, clover and pea, very much smaller quantities being detected in the roots of the same plants. Shaikat-Ahmed and Evans<sup>6</sup> reported that *Ochromonas* assay of nodules from soya bean plants supplied intermittently with 0.05 p.p.m. of cobalt indicated the presence of 619 mg vitamin B<sub>12</sub> per g of fresh nodules. By enzymatic assay, Klierer and Evans<sup>7</sup> found appreciable amounts of vitamin B<sub>12</sub> co-enzyme(s) in the nodules of various legumes grown in the presence of the above level of cobalt.

Klierer and Evans also reported the presence of vitamin B<sub>12</sub> co-enzyme(s) in the root nodules of the non-legume *Alnus oregona*, while Bond and Hewitt<sup>8</sup> provided evidence of the necessity of cobalt for the proper functioning of the nodules of *Alnus glutinosa*, and in unpublished work have extended this finding to species of other non-legume genera with nitrogen-fixing root nodules. The question thus arose whether in these further species cobalt is elaborated in the nodules into the form of vitamin B<sub>12</sub> analogues. Data on this aspect are now presented.

Samples of nodules and also of roots of five non-legume species were taken, during the period July to September, 1963, from plants growing in the greenhouse in non-aseptic culture. The plants of *Coriaria* were grown in vermiculite, those of the other species in water culture, the culture solution employed being that of Crone (nitrogen-free formula). Cobalt was supplied intermittently at 0.015 p.p.m., while in addition there may have been a further quantity present as impurity in the salts used in preparing the culture solution since these were not specially purified. Root samples were included in order to permit comparison between the nodules and a normal part of the plant. The roots selected were from the same plants

as the nodules, though roots which had actually borne nodules were avoided. Nodule samples from two legumes were also included for comparative purposes, and were taken from garden plants. After being washed in water, the nodule samples (usually 1 g) were homogenized as completely as possible with 100 ml. distilled water in a Waring blender. With roots a larger sample (usually 10 g) was similarly treated. The homogenates were placed in a deep freeze until required for assay.

The microbiological assay procedure was that described by Hutzner, Bach, and Ross<sup>9</sup> using commercially available medium (Difco) and *Eruglena gracilis* 'Z' strain as the test organism. The samples were assayed against aqueous standards of pure cyanocobalamin. Various dilutions were assayed until a suitable dilution was found, and the results given below are the mean values of two or more assays of such a dilution. Different extraction procedures were tried: (1) the homogenate from the Waring blender was used direct, (2) it was subject to further ultrasonic homogenization, (3) its pH was adjusted to 4.0 and potassium cyanide was added to give a concentration of M/100, after which the mixture was boiled for 15 min, (4) the original homogenate was digested with pancreatin, papain, or ficin. The results obtained by these various procedures with a given sample varied considerably, but the only consistent difference found was that the yield of active substances from root samples was much increased when cyanide was used.

The results obtained by two of the extraction procedures are presented in Table 1. Although the data are shown in terms of vitamin B<sub>12</sub>, it is appreciated that *Eruglena* also responds to pseudo-vitamin B<sub>12</sub> (ref. 10) and (in our experience) to hydroxocobalamin and to at least one of the cobalamin coenzymes in addition, so that it is uncertain to which of these substances any activity shown by the extracts was due.

Table 1. RESULTS OF *Eruglena* ASSAYS  
mg vitamin B<sub>12</sub>/g fresh tissue

Species	Stage of plant development	Nodules		Roots	
		(1)*	(2)*	(1)*	(2)*
<i>Casuarina cunninghamiana</i>	2nd yr.	211	367	0.36	5.5
	1st yr.	307	219	<0.25	<2.5
<i>Alnus glutinosa</i>	2nd yr.	63	185	<0.25	3.4
	1st yr.	181	236	<1.0	<10.0
<i>Myrica gale</i>	2nd yr.	55	85	<0.25	<2.5
	1st yr.	207	185	11.6	23.8
<i>Hippophae rhamnoides</i>	2nd yr.	28	53	4.5	23.4
<i>Coriaria myrsinites</i>	Flowering	238	134	—	—
<i>Pursh sativum</i>	Young pods present	233	254	—	—

\* Numbers refer to extraction procedures (see text).

The data indicate that considerable amounts of one or more of these vitamin B<sub>12</sub> analogues are present in the non-legume nodules, the levels in *Casuarina* and *Hippophae* nodules and in those from first-year plants of *Alnus* and *Myrica* being of the same order as in the legume nodules. The occurrence of active substance is not entirely restricted to the nodules, since some was detected in root samples, especially those of *Hippophae* and *Coriaria*. In a preliminary survey in summer, 1962, a number of samples were assayed using extraction method (1) only. The results were in general similar to those reported here.

The much greater abundance of active substance in the nodules as compared with the roots (except in *Coriaria*) can undoubtedly be attributed to the extensive development within the nodules of the endophyte, which is almost certainly of actinomycoete affinities. It is well known that organisms of this group are active producers of vitamin B<sub>12</sub> analogues. It remains to be seen whether the necessity of cobalt for the proper functioning of these non-legume nodules is due to some essential part played by vitamin B<sub>12</sub> substances.

The activity found in the roots has three possible origins: (a) by leakage from the nodules into the roots; (b) production by contaminant micro-organisms growing on the surface of the roots; (c) synthesis by the root cells

themselves. Whether the cells of higher plants have such a capacity is a moot point<sup>11-13</sup>.

### Heritability of Heartwood Formation in *Pinus radiata* D. Don

AN important change which occurs in the wood of most trees as they grow older is the transformation of sapwood into heartwood. This change is associated with the death of the ray and vertical parenchyma cells, and definite modifications to the anatomy of both softwoods and hardwoods<sup>1</sup>. As a result, heartwood is more difficult to season, is less readily penetrated by preservatives and pulping liquors, and resinous extractives are troublesome.

Schreiner<sup>2</sup> could not find conclusive evidence of the inheritance of heartwood formation, while Harris<sup>3</sup> thought that the genetical constitution, age and ecology of a tree together contribute to the formation of heartwood in the stem. The latter suggested that a 'heartwood forming' tendency is genetically controlled, but that environment also plays an important part.

The most useful investigation of the inheritance of a characteristic should yield a quantitative measure of the intensity of genetic control. Such a measure is provided by a ratio called 'heritability'<sup>4</sup> which considers genetic variability in relation to phenotypic variability. This term is used in either a broad or narrow sense depending on whether the total or only the additive portion of the genetic variability is taken into account.

In an investigation of this kind it is not practical to investigate the variation in the age at which heartwood begins to form in the tree. Therefore the amount of heartwood was used as the basis for calculating estimates of gross heritability from results derived from trees of a clonal plantation.

Thirteen clones from a plantation of *P. radiata*, established in 1930, in the Australian Capital Territory were sampled by selecting the first, middle and last trees of the row comprising the clone. Only vertical trees were chosen. Increment cores were taken from each tree in the north and the south directions at heights of 1.2 m and 4.6 m.

In a mature cross-sectional disk of *P. radiata*, the coloured heartwood adjacent to the pith and the narrow transition zone, which also contains heartwood substances<sup>5</sup>, stain a deep orange-brown on the application of a diazotized benzidine stain<sup>6</sup>, in contrast to a yellowish stain for the sapwood. This staining technique was used to differentiate the heartwood and transition zone from the sapwood, because the natural colour changes could not be seen clearly in the small samples used.

Because of differences in the pattern of early height growth, sampling at fixed heights in trees produces speci-

mens with differing ring counts. Consequently the growth ring showing the furthest extent of heartwood from the pith could not be used as a comparative measure of heartwood content, and it was decided instead to use the area proportion of heartwood. This was possible because of the poor correlation between specimen ring count and proportion of heartwood in these results. Therefore, the radial extent of the heartwood and the tree radius were recorded for each specimen, so that values for the opposite radii at each height could be averaged and used to express the heartwood area as a proportion of the total cross-sectional area for each sampling height in each tree.

The variation in heartwood content between trees was separated by analysis of variance into within-clones and between-clones components and gross heritability estimated as :

$$\frac{\text{between-clone variance}}{\text{between-clone variance} + \text{within-clone variance}}$$

Estimates of gross heritability for the proportion of heartwood were as follows :

Height (m)	Gross heritability estimate significant at 5% level	S.E.
1.2	0.37	0.18
4.6	0.36	0.18

The value of 0.37 is not very large compared with the estimate of 0.73 obtained for average fibre length on clonal material from the same locality by Dadswell *et al.*<sup>7</sup>. Little gain could therefore be expected to result from the use of seed from parents selected for low heartwood content, and even if vegetative propagation methods were used, the gains achieved would be worthwhile only if the absence of heartwood was very critical to the final product.

It should be stressed that the work recorded here is based on results from 13 clones from a single area. However, the lack of heritability estimates for many wood features is keenly felt and there is some justification for publishing preliminary values in the hope that they may be augmented by others to provide better estimates based on pooled results.

I thank the Director-General, Forestry and Timber Bureau, Canberra, for making available the wood specimens, and particularly Messrs. A. G. Brown and J. M. Fielding for arranging for their collection. I also thank Misses J. Down and J. Sibthorpe for carrying out the detailed measurements on which the results of this investigation have been based, and Miss N. Ditchburne, C.S.I.R.O. Division of Mathematical Statistics, for help in the statistical analyses.

## ENTOMOLOGY

### Purification of the Fire Ant Trail Substance

THE fire ant, *Solenopsis saevissima* (Fr. Smith), utilizes a trail substance as an aid in effective foraging<sup>1</sup>. Workers secrete a substance from the Dufour's gland which is deposited from the sting in the form of minute streaks. These mark a trail from a suitable food source to the nest. Workers are strongly attracted to this substance and follow the trail outward to the food source. The newly recruited workers in turn lay trails to the nest, reinforcing the original trail. The appropriate properties for effective trail substances have been discussed by Bossert and Wilson<sup>2</sup>.

## Culture in London Study in Melbourne

An efficient method of transporting living cells and other specimens has become one of the biologists' most urgent needs. Now Union Carbide has developed a revolutionary new range of biological transporters embodying a unique principle of cryogenic storage which enables the temperature of the specimens to be kept below  $-130^{\circ}\text{C}$  for up to five days: long enough for a train journey across Europe or a freight flight from London to Australia. The new transporters consist of an aluminium outer shell with a plastics lining containing a porous specimen holder drilled to accommodate the

specimen ampoules. This holder is saturated with liquid nitrogen which gradually evaporates and is exhausted to atmosphere through pressure relief vents. The porous specimen holder eliminates the danger of spillage, and Super Insulation reduces the evaporation rate to 0.33 litres per day in the case of the BT-2 and 0.38 litres per day in the case of the larger capacity BT-3. Porous holders can be supplied to fit any shape of specimen container. Since the BT-2 holds 1.6 litres of nitrogen and the BT-3 2 litres, both transporters have a guaranteed static holding time of 5 days.

WCW 33ER

The trail substance of *S. saevissima* has been purified in the hope of learning something of its chemical properties. For a qualitative assay during purification, wooden splints were dipped into solutions of the fractions to be tested and the splints drawn across a smooth surface near a laboratory colony of *S. saevissima*. Activity was estimated by rough counts of the number of workers which were attracted to and followed the artificial trail.

Workers of *S. saevissima* were collected near Jacksonville, Florida, in the following manner. The nests were quickly spaded into buckets and the sandy contents were poured into still water. Most of the sand and debris sank, while a considerable number of ants rose to the surface, where they aggregated and floated in clumps. The ants were gathered with a tea strainer and transferred to bottles which contained dichloromethane.

Ants (approximately 200,000 workers), along with water, dichloromethane and remaining debris, were poured into a large flask and the whole mass was steam distilled into an ice-cooled receiver until attractive material ceased to distil. For a volume of 1,500 ml. in the distillation flask, about 3 l. of steam distillate (water and dichloromethane) was obtained. This was repeated six times to process all the collected material. The active material could be extracted from the aqueous phase of the steam distillate with dichloromethane. Three extractions of 3-l. portions of the distillate with 200-ml. portions of dichloromethane removed all the attractive substance. The dichloromethane phases were dried over anhydrous sodium sulphate. After filtration the dichloromethane solution could be concentrated cautiously in a distillation flask at atmospheric pressure without extensive loss of active material. In this way 4 l. of solution were reduced to a volume of 2 ml.

Attempts to purify the trail substance by adsorption chromatography on alumina or silicic acid were ineffective, and either resulted in complete loss of the active material or in no adsorption of the active material on the column. Exploratory experiments with gas-liquid chromatography indicated that the active compound could be recovered from columns when polydiethyleneglycol succinate was used as a liquid phase. When the temperature of the column was increased from 50° to 200° at the rate of 5°/min, the active material was collected over the range of 125–140°.

For purification of the trail substance, a column 8 ft. by 0.25 in. packed with 5 per cent polydiethyleneglycol succinate on 'Chromosorb W' was operated at 135° in a Research Specialties model '600' apparatus, equipped with an argon detector. Aliquots (50 µl.) were injected and the effluent compounds were collected in cooled U tubes. The process was repeated until the whole 2 ml. sample had been chromatographed. Fig. 1A shows the chromatogram obtained in this fashion. The collected material was chromatographed a second time (Fig. 1B) to yield homogeneous material. In Fig. 1C, the pure sample is compared with geraniol, which was used as a standard for the calculation of a relative retention time and for estimation of mass. The apparently homogeneous trail substance has a retention time relative to geraniol of 0.8, and the total sample contained about 250 µg of material.

While it is clear that the active material is contained within the peak observed by gas chromatography, the sample may still be contaminated with a large amount of an inactive compound with similar chromatographic properties. Williams and Law<sup>3</sup> have recently shown that a highly purified insect hormone, which gives essentially one peak on gas chromatography, still represents a small amount of active material in the presence of a large amount of an inactive compound.

Considerable losses of active material were encountered in the purification procedure. Furthermore, it was found that either crude or purified material rapidly lost activity, even when stored at –20° in dichloromethane. A sample of the apparently homogeneous material lost about 80 per

Fig. 1. Chromatographic purification of the fire ant trail substance. The chromatographic column was operated at approximately 135°. Slight variations in temperature and pressure caused the differences in retention time shown in the three curves. Curve A, crude steam distillate. Curve B, active fraction collected from the first chromatographic step. Curve C, pure trail substance collected from two passes on the chromatographic column, compared with geraniol. 10 µg of geraniol was mixed with 1/100 of the total trail substance sample. Comparison of the peak areas indicates that about 8–5 µg of material is present in the trail substance peak.

cent of its activity when stored for three months at –20° C in dichloromethane. The peak observed by gas-liquid chromatography also decreased in area by a similar proportion. A second large batch of crude material representing about 300,000 ants lost almost all activity when stored for two months in dichloromethane at –20°.

While this undesirable behaviour causes some frustration in attempts to identify the active trail substance, it also indicates the possibility that chemical instability may play a part in obliterating the trail substance after it has served its function. Wilson<sup>4</sup> has previously suggested that this is accomplished by using a very volatile material for a trail substance. However, it cannot be ruled out that the substance may also be inactivated by chemical reaction with some substance in the environment, such as oxygen or water.

## Gland-like Abdominal Structures of Possible Epigamic Function in the Diptera

RECENTLY one of us<sup>1</sup> erected a new genus, *Austrodrapetis*, to receive an undescribed empidid fly from the Cook Islands. Striking features of this species were the presence of abdominal structures of unknown function in the male coupled with certain secondary sexual characters in the coxae of both sexes and the tibiae of the male.

The abdominal organs (Figs. 1a and b) are in two pairs beneath the third and fourth terga. There is no apparent opening to the surface, but a small one may be present in view of the duct-like anterior region of each organ. The organs seem too strongly sclerotized to be eversible especially as there is no obvious opening to the surface. There is no apparent connexion between the organs and any of the few large tracheal trunks in their vicinity. The

## CYTOLOGY

## Ribosome Numbers in a Fission Yeast

THERE is a need for a more confined and precise use of the word ribosome. It would clarify molecular biology if the word were reserved for particles in the cell which measure 100 Å–300 Å in diameter, are composed of RNA and protein, and have been shown to be active as sites for the synthesis of proteins. However, such criteria are not easily available to, say, an electron microscopist. This communication describes an attempt to compare the number of ribosomes in a cell, as calculated from biochemical data, with the number of particles in the same cell type, visible in the electron microscope after osmium tetroxide fixation, and, in terms of size and distribution, categorized as ribosomes in contemporary electron microscopy.

The cell used in this work was a fission yeast, *Schizosaccharomyces pombe*. An electron microscope investigation of this cell has already been published<sup>1</sup>, and the RNA content in a variety of growth conditions is known<sup>2</sup>. *S. pombe* (National Collection of Yeast Cultures, 132) is a small yeast, cylindrical in shape, with the ends of the cell hemispherical, varying between 5 and 15 μ in length, and maintaining a fairly constant diameter of 3.5 μ. All cells used were growing vegetatively, cultured in 2 per cent w/v Oxoid 'Wort Broth' (malt extract broth) in distilled water, and in the exponential phase of growth from cultures containing between 3 and 6 × 10<sup>6</sup> cells per ml. Cultures were grown at 33° C (the generation time at this temperature is slightly more than 2 h) in 400 ml. of medium in 1-l. conical flasks, with no agitation or aeration.

Since *S. pombe* grows, in general, only in length, an estimate of the stage of a single cell in the cell cycle can be assessed from its length. But if lengthwise measurements are to be made on sections viewed in the electron microscope, it is essential that the sections be truly longitudinal. This implies that the cells must be aligned in the embedding procedure so that they are flattened in a monolayer and present their total length to the microtome knife. The following method of preparation was used.

Cells were gathered by centrifugation, washed twice in 0.25 M sucrose buffered with veronal acetate at pH 7.2, and spun down in the sucrose to a concentration of 2 × 10<sup>6</sup> cells per ml. Drops of this suspension were now placed on square cover slips, size 1, and the solution evaporated almost, but not quite, to dryness. With the cover slips in a glass Petri dish, cells uppermost, and some 8 cover slips per dish, drops of 2 per cent osmium tetroxide in the buffered sucrose were applied in sufficient quantity to flood each cover slip, and the Petri dish cover put in place. After 30 min at room temperature, the Petri dish cover was removed and the dish flooded with distilled water. Numerous washings with water were carried out, followed by washings in increasing concentrations of alcohol, and ending with three washings in absolute alcohol. The cover slips were not moved during this procedure. Following this dehydration, the Petri dish was flooded once with liquid methacrylate, which, on removal, was replaced by a final pool of liquid methacrylate which consisted of 91 per cent butyl methacrylate, 8 per cent methyl methacrylate and 1 per cent benzoyl peroxide. Polymerization was carried out at 58° C with the Petri dish cover in place, and was normally complete in 24 h.

After polymerization, the bottom section of the Petri dish was splintered with a hammer and removed, leaving a flat block of plastic with the cover slips applied to the flattened surface. The cover slips were removed by contact with solid carbon dioxide, causing them to break away from the plastic. With the cover slips removed, the monolayer of cells which had been applied to them is found embedded in the plastic surface. Groups of cells are located on the surface by a low-power microscope and

Fig. 1

organs are hollow and the inner surface of the outsole is produced into hair-like structures interspersed with some shorter blunter processes (Fig. 1c).

It is possible that these are scent-producing glands, perhaps defensive, but more probably epigamic. The presence of numerous hairs within the cavity and the setose area on each segment between the two 'openings' would be an efficient method of conducting any liquid secretion to the exterior and providing it with a large surface area for evaporation. The position of the organs, fairly close behind the wings, would also ensure an efficient dispersal of the scent in the alipstream.

Feuerborn<sup>3</sup> has described glandular organs of probable epigamic function on the thorax of some Psychodidae (again behind the wings). Lamb<sup>4</sup> has described some curious structures in the basal abdominal segment of males of the dolichopodid fly *Oraterophorus mirus* Lamb and it may be significant that the structure of the squamae and the shape of the hind-margin of the wing are modified, perhaps affecting the alipstream. Parent<sup>5</sup> has also described abdominal organs of unknown function in *Syntormon* (Dolichopodidae) from New Zealand. Edwards<sup>6</sup> has described eversible glandular structures in the abdomen of females of the midge *Palpomyia brachialis* Hal. The females of this midge dance in swarms with the abdominal glands everted and males fly into the swarms, the paired insects then dropping out to mate. Later Edwards<sup>7</sup> reported these glands as occurring throughout the genera *Palpomyia* and *Bezzia*. Scent-distributing organs occur widely in the Lepidoptera (*vide* Varley<sup>8</sup>, Philpott<sup>9</sup>), but are usually of more elaborate structure. A comparative study of sense organs in the antennae and palpi of Diptera has been published<sup>10</sup>, and we suggest that a comparable study of abdominal structures would be a suitable topic for further investigation.

0.25-in. cubes of the plastic are cut from these areas, and trimmed under the microscope to leave a flat face of about 1 mm square to be presented to the microtome blade. Great care was necessary in cutting these blocks, since, if the microtome was not properly set, all the cells could be lost in a few primary sections which were too thick to be of use. The plastic blocks were held in a small chuck for cutting in a Huxley microtome and sections were floated on to a water reservoir, expanded with xylene vapour, and picked up on carbon-coated grids in the usual way. Sections showing silver interference colour were removed for examination in the microscope.

Numbers of ribosomes per cell were calculated from sections in the following way. Since a certain degree of detail and contrast was invariably lost in printing and enlarging the photographic plates, the ribosome counts were made by direct examination of the plates themselves. Using a high-power hand lens for examination, plates taken at instrumental magnifications of 20,000 were illuminated from below by means of a cold light illuminator, and particle numbers and distribution determined by placing a transparent plate, marked off in 1 mm squares, over the photographic plate. By this means a cell section at a magnification of 20,000 was subdivided into some 1,400 squares, permitting assessment of the comparative area occupied by cytoplasm, nucleus and vesicles, and the distribution and absolute numbers of the ribosomes themselves. Actual counts of ribosome distribution and numbers were made by numbering the squares on the grid and counting the ribosomes in 40 squares per section, the squares for examination being selected at random by the use of random number tables. Squares falling entirely or partly on cell organelles (nuclei, vacuoles and vesicles) were omitted from counts, and particles on the line were scored on only two sides of the square. The standard deviation of ribosomes per square was  $\pm 0.1$  to  $\pm 0.5$  for 40 counts, and the mean of 40 squares multiplied by the total number of squares covering cell, minus cell wall, gives the figure for total numbers of ribosomes per section. It was assumed that all cell sections examined represented 800 Å of the cell when cut<sup>2</sup> and thus the number of particles per section was multiplied by 37 to give the number per cell, an average cell thickness, minus cell wall, being taken as 3µ. Shrinkage of the cells during preparation and examination appeared to be slight and was ignored. Using the grid plate examination technique described, the ratio of mean area of cytoplasm to area of nucleus and cell inclusions was found to be 9-1, and the total ribosome number per cell was assessed for 100 per cent cytoplasm and rectified in accordance with this ratio.

The ribosomes of *S. pombe* appear to be freely dispersed in the cytoplasm<sup>1</sup>, and all darkly stained particles in the cytoplasm of about 150 Å diameter were scored as ribosomes. Of course, the number of assumptions inherent in this counting scheme is considerable, as are the possible sources of error, for example, deviation from the estimated ratio of volume of cytoplasm to volume of cell inclusions, varying cell thickness, thickness of section, and visibility of ribosomes, and the possible existence of ribosome dimers scored as single ribosomes.

Fig. 1 shows the number of ribosomes calculated from the electron micrographs as being totals per cell, plotted against cell length of the section. From this figure it would seem that an average cell of *S. pombe* in logarithmic growth possesses about 500,000 ribosomes. Although it would be of considerable interest to know the variation in ribosome numbers during the cell cycle, the inadequacy of the results presented in Fig. 1 does not permit drawing any conclusions on this question.

Since the sum of the molecular weights of the RNA molecules in a single ribosome is believed to be about  $1.7 \times 10^6$  for a 70 or 80 S ribosome<sup>4</sup>, it is possible to calculate that such a ribosome must contain  $2.7 \times 10^{-18}$  g of RNA (using Avogadro's number). With 500,000

Fig. 1. Total numbers of ribosomes in *S. pombe* cells of different sizes

ribosomes in a cell, a cell of *S. pombe* should possess  $1.35 \times 10^{-13}$  g of ribosomal RNA, and assuming 80 per cent of the total cell RNA to be ribosomal,  $1.7 \times 10^{-13}$  g of total RNA. Mitchison and Lark<sup>3</sup>, using biochemical methods, have determined that *S. pombe* cells in logarithmic growth at a cell density of  $5.7 \times 10^6$  cells per ml. contain  $2.13 \times 10^{-13}$  g RNA. These results show that, at least on numerical grounds, there is some basis for believing that the ribosomes of the electron microscopist and the biochemist are the same particles.

This work was carried out during the tenure of a scholarship from the Medical Research Council, London. I thank Prof. J. M. Mitchison and Dr. P. M. B. Walker for their advice.

## VIROLOGY

### Morphology of Components of Sendai Virus

It has been shown by using a negative contrasting method that Sendai virus particles have an envelope which is formed of spikes of haemagglutinin and covers a tubular nucleocapsid with a diameter of helix of about 170 Å<sup>1</sup>. Sub-units of this virus (*S* and *V* antigens) resemble those of other myxoviruses, particularly of Newcastle disease virus<sup>2,3</sup>.

We have examined some details of the structure of Sendai virus in native and purified preparations treated by several methods. 11-day-old chick embryos were infected by the allantoic route with 100-1,000 *ID*<sub>50</sub> of the LM-1 strain of Sendai virus; the latter was collected after incubation at 35°C within 72 h. Allantoic fluid virus, native and purified by differential centrifugation and subsequent 'Sephadex'-gel filtration<sup>4</sup>, was examined in an electron microscope.

To reveal the structure of virus particles the preparations were treated with ethyl ether and trypsin. Ethyl ether was refined and freed from hydrogen peroxide, added gradually to an equal volume of virus preparations at 17°C in a glass with magneto-mixer. A layer of ether was removed after centrifugation at 1,600 r.p.m. for 15-20 min, and water suspension was freed from ether by passing gaseous nitrogen. In experiments with trypsin a crystalline enzyme was added to virus suspensions in 0.007 phosphate balanced solution, pH = 7.8, so that concentration of enzyme and substrate related as 1:50. Specimens were taken at intervals of 30 min for haemagglutination tests and electron microscopic examination.

Preparations for electron microscopy were prepared by means of thermal fixation<sup>4</sup>. Our modification<sup>5</sup> of the Brenner and Horne<sup>6</sup> negative contrasting method was used.

Besides the usual tubular structures of the nucleocapsid which are characteristic for this virus, we have found rod-like structures about 380 Å in diameter and 2500–3000 Å in length (Fig. 1). They are not sensitive to treat-

Fig. 1. A particle of Sendai virus. Usual helical rod-like structures and a wider structure (arrow). Negative contrasting with phospho-tungstic acid,  $\times c. 200,000$

Fig. 2. A preparation of Sendai virus after treatment with trypsin. Helical rod-like structures and a wider structure partly released from a capsule. Negative contrasting with phospho-tungstic acid,  $\times c. 187,000$

Fig. 3. A preparation of Sendai virus after treatment with ethyl ether. Secondary arrangement of haemagglutinin. Negative contrasting with phospho-tungstic acid,  $\times c. 100,000$

ment with trypsin which destroys the external envelope of the virus. In preparations treated with trypsin one can see clumps of viral envelopes, granular substrate, rod-like helical structures of nucleocapsid and the structures mentioned above which have also a helical structure with the angle of pitch about  $45^\circ$  with a partly destroyed capsule (Fig. 2). In preparations treated with ether these structures lose the capsule, which points to the latter being of lipid nature.

After treatment with ether, viral particles are decomposed into their components, and secondary aggregates of haemagglutinin are formed around dense masses of viral material which resemble a typical spike-like arrangement of haemagglutinin at the surface of intact virions (Fig. 3).

These results lead to the conclusion that structurally the nucleocapsid of Sendai virus, besides the usual rod-like dense helical forms, occurs also as more crumbly (pasty) packing which possesses lipotropic properties. The secondary aggregates of haemagglutinin as a typical palisade of spikes demonstrate a self-assembly process which probably occurs during the formation of virions.

### Determination of the Type of Nucleic Acid in Rubella Virus using 5-Bromo-2'-deoxyuridine

SALZMAN<sup>1</sup> showed that 5-fluoro-2'-deoxyuridine (5-FUdR), when added to virus-tissue culture systems, specifically inhibited the synthesis of DNA viruses but did not affect RNA virus or protein synthesis. The inhibition could be reversed by the addition of excess thymidine. The use of 5-FUdR, or one of its analogues, thus provides an indirect test of whether a virus contains DNA or RNA. An advantage of such a test is its rapidity when compared with conventional techniques of nucleic acid isolation and purification; but in order to avoid misleading results the final concentration of the analogue<sup>2</sup> and the serum content of the tissue culture maintenance medium must be carefully controlled<sup>3</sup>. Media prepared with high concentrations of serum or embryo extract may contain enough thymidine to cause partial reversal of the inhibitory action of the analogue.

The object of the work recorded here was to use 5-bromo-2'-deoxyuridine (5-BUdR) in an attempt to determine the nucleic acid type of rubella virus. The experiments were controlled by testing the effect of 5-BUdR on the growth of two known DNA viruses (adenovirus type 7 and herpes simplex) and an RNA virus (coxsackie A21). The specificity of the effects of 5-BUdR was controlled by seeking reversal of inhibition on addition of thymidine.

Recently, several reports have appeared of isolations of strains of virus from patients with rubella<sup>4-6</sup>. Investigations of the biological characteristics of these strains are, as yet, incomplete, but the information available indicates that they form a serologically homogeneous group. The rubella strain<sup>7</sup> selected for use in the work described here appears to have biological features typical of the group.

Table 1

Virus	Tissue culture system	Tissue culture maintenance medium	Titre of virus inoculum TOID <sub>50</sub> /ml.	Time of virus adsorption (h at 37° C)

Rubella‡	RK <sub>13</sub> (ref. 6)	Medium 199+2% calf serum	10 <sup>4.5</sup>	4

\* Five-day end-point reading.  
† and ‡ strains obtained from Virus Reference Centre, Colindale.  
‡ Obtained from Dr. J. S. Porterfield.

The tissue culture system and composition of the maintenance medium used for each virus are shown in Table 1. Preparation of tissue cultures was by conventional methods<sup>6</sup>. For each virus, three parallel growth curve experiments were carried out under the following conditions: (1) in cells with maintenance medium only; (2) maintenance medium + 5-BUDR ( $6.5 \times 10^{-4}$  M); (3) maintenance medium + 5-BUDR ( $6.5 \times 10^{-4}$  M) +

Fig. 3. Multiplication of adenovirus type 7.  
Key, as Fig. 1

thymidine ( $4.1 \times 10^{-4}$  M). In each case the tissue cultures were treated for 24 h with the appropriate maintenance medium prior to inoculation with virus. Replicate test-tube tissue cultures were inoculated with a measured dose of virus and, after a period of virus adsorption (Table 1), residual virus was removed by three washings with Hanks's saline. At selected time intervals, sample groups of tissue cultures were collected by subjecting them to three cycles of freezing and thawing to release cell-bound virus, and the fluids centrifuged (2,000 r.p.m./6 min) and afterwards pooled. Infective virus in the pools was assayed using end-point infectivity titrations<sup>6</sup>.

The growth curves are shown in Figs. 1-4. The multiplication of DNA-containing herpes simplex and adenovirus type 7 was completely suppressed in the presence of  $6.5 \times 10^{-4}$  M 5-BUDR. This inhibitory effect of 5-BUDR was reversed by the addition of thymidine. Thus, herpes simplex virus (Fig. 1) multiplied rapidly 24-60 h after

adsorption both in cells treated with thymidine + 5-BUDR and in control cells maintained with normal medium. No infectious virus was detected over the experimental period in cells treated with 5-BUDR alone. The growth curves for adenovirus type 7 (Fig. 2) are similar to those for herpes simplex and confirm these results for a more slowly multiplying DNA virus in an alternative host cell system.

In contrast, 5-BUDR at the same concentration had no detectable effect on the growth rate or final yield of coxsackie A21 virus (Fig. 3). The multiplication of rubella virus (Fig. 4), similarly to coxsackie A21, was not inhibited to any measurable extent in the presence of 5-BUDR. The most active period of rubella virus multiplication, 24–72 h after adsorption, and the final virus yield, were the same in 5-BUDR-treated cells and in cells maintained in normal medium. The strain of rubella virus tested thus clearly behaved as an RNA-containing virus.

We thank Dr. G. Schild and Profs. C. P. Beattie and C. H. Stuart-Harris for their advice, and Chas. Pfizer for gifts of Medium 199. This work was supported by a Medical Research Council Scholarship.

*Note added in proof.* Since this communication was submitted for publication, H. F. Maassab and K. W. Cochran have reported similar results using the fluorochrome analogue and an indirect viral interference method of estimating the growth characteristics of rubella virus (*Proc. Soc. Exp. Biol. and Med.*, 117, 410; 1964).

### Reproduction of the Viruses Isolated from Cases of Infectious Hepatitis on Detroit-6(VA) Cell Line

In this report we propose to study certain aspects of the reproduction of viruses isolated from cases of infectious hepatitis<sup>1–4</sup> and at the same time to demonstrate their aetiological role in the development of this disease.

Between 1957 and 1964, we have studied a total of 21 different strains of infectious hepatitis viruses. These viruses were isolated on Detroit-6 cells, while 4 strains (R, V9, V6, 163 S) were adapted to a variant of the Detroit-6 cell line, obtained in our laboratory and given the name of Detroit-6(VA). In the course of our investigations we used a culture medium consisting of two parts of Earle's medium, one part of synthetic medium M 199, and calf serum, at a pH of 7.6. The infected cell cultures were maintained for ten days at a temperature of 37° C on a roller-tube apparatus, and for an additional four days on a stationary stand. With each strain of virus we made 40 successive passages. In order to study the modifications of the cells, they were included in a methacrylate or 'Vestopal' base, sectioned with the aid of a Reichert-type ultramicrotome and examined on a TESLA 'BS 242 A' electron microscope.

Complement fixation reaction and neutralization tests were applied for the serological identification of the isolated virus strains.

Four days after inoculation of the Detroit-6(VA) cells with the virus of infectious hepatitis, we observed swelling, rounding-off of the marginal cells, and the formation of aggregates—a phenomenon which appears after ten days in the form of foci, on the entire surface of the culture. Later on, the affected cells degenerate and detach from the walls of the test-tube; meanwhile the other cells, which have not previously shown any sign of degeneration, are also damaged. The most notable changes are observed 14 days after inoculation, the controls remaining unaffected.

Four days after inoculation, electron micrographs showed the aggregation of dense particles within the nuclei and the appearance of very small granules along the whole length of the nuclear substances. The nucleolus remained unaffected. In the cytoplasm there was an accumulation of dense granular material, similar to, and presumably identical with, the viroplasm, from which the virus particles form.

Ten days after inoculation the granular substance of the nucleus became rarefied, with the appearance of individualized dense granules of approximately 200–300 Å, dispersed irregularly in the nucleoplasm. During this period the cytoplasm shows a marked vacuolation, with diminished mitochondria (compared with the control cells), and loss of internal structure. The endoplasmic reticulum is imperceptible. During this phase we should like to emphasize the appearance of dense corpuscles about 150 Å diameter, occurring in compact masses, most frequently in formations of 4–6 particles, with the form of a rosette with a hollow centre, which fill parts of the cytoplasm, without a regular distribution. On the 14th day the rosette-like formations become prominent within the cytoplasm and acquire a symmetrical arrangement in parallel lines (Fig. 1).

Similar particles were also detected in the liver of patients suffering from infectious hepatitis. The supernatant fluid of the Detroit-6(VA) cells, infected with R and 163 S viruses after purification, contains certain formations similarly formed by 4–6 small particles. These formations appear to attain a similar size, about 150 Å, in all the strains of viruses studied. This results in the accumulation of RNA in the cytoplasm (studied with an acridine-orange staining), the particles resisting treatment with ether, as well as a temperature of 60° C.

The complement-fixation reaction made with the viruses isolated by ourselves, and the sera of 260 patients suffering from infectious hepatitis, proved to be positive in 91 per

Fig. 1. Detroit-6(VA) cell, infected with the 163 S strain of hepatitis virus. The arrow indicates the symmetrical arrangement of the viruses ( $\times 17,500$ ).

cent of cases. The seroneutralization of the virus with 32 sera of convalescent patients indicated that there is a certain serological relationship between all our strains of viruses, although frequently the titres were quite low. Even so, in two cases titres of 1 : 640 were obtained.

From these findings, and from the fact that two accidental infections occurred in the laboratory due to two strains (R, V9), and having regard to the typical clinical symptoms of infectious hepatitis and the fact that it was possible to re-isolate these viruses, as well as to neutralize them, by the patients' sera, we consider these agents to be the viruses of infectious hepatitis.

Rightel *et al.*, Taylor *et al.* and Bearcroft have described similar viroic particles in the cell culture<sup>4,5</sup> and in the liver of patients suffering from infectious hepatitis<sup>4-7</sup>. These particles are very similar to those noted in the Detroit-6 (V4) cells inoculated with the strains of viruses isolated in our laboratory.

## Effect of 5-Fluorodeoxyuridine on the Replication of Tobacco Mosaic Virus in Meristematic Tissue

THE phenomenon by which plant viruses are excluded from proliferating cells may prove to be a valuable means for investigating the mechanism of plant virus replication itself.

It has been shown that incubation of young tomato plants in ethylene diaminetetraacetic acid (EDTA) supplemented medium enables tobacco mosaic virus (TMV) to replicate in root apical meristem, from which it is normally excluded, and it has been suggested that this compound acts by degrading microsomal particles, thus furnishing building blocks for virus formation<sup>1</sup>. On the other hand, TMV replication in leaf disks of *Nicotiana glauca* was depressed by kinetin, a compound known to promote cell proliferation<sup>2</sup>, suggesting that conditions favouring proliferation may prevent virus formation. One of the processes which is obviously correlated to cell proliferation is DNA synthesis itself, and accordingly, the effect of inhibition of this process on the capacity of meristematic cells to sustain TMV replication was investigated.

In this communication, results are presented demonstrating replication of TMV in root tips of young tomato plants incubated with 5-fluorodeoxyuridine. This compound is known to inhibit synthesis of DNA in other systems<sup>3,4</sup> but to have little effect on the formation of TMV in excised leaf disks of Turkish tobacco<sup>5</sup>. Three to five 3-week-old tomato plants grown in soil were transferred to each of a series of 100-ml. jars containing 25 ml. Knopp solution. Twenty-four hours later, substances, the effect of which was to be examined, were added to the jars in the following final concentrations: EDTA,  $6.4 \times 10^{-4}$  M; and FUDR,  $7.6 \times 10^{-4}$  M. After 18 more hours, all plants were infected with TMV (isolate 'Mostar') by rub-

bing leaves with a purified suspension of virus. One week later, root tips, 0.5–0.7 mm long, were collected from the plants. From each category, 25–30 mg of root material was taken and homogenized in 0.7 ml. of a 0.1 M phosphate buffer, pH 7.0, and shaken in chloroform for 30 min. To estimate the concentration of virus particles, 0.6 ml. of each homogenate was used to infect a total of 4 leaves of the test plant *Nicotiana glauca*. After five days, the number of local lesions was counted. Table 1 gives the results, and shows the effect of EDTA and FUDR on the ability of infected plants to promote virus replication in root tips.

Table 1. TOTAL NUMBER OF LESIONS PER 4 LEAVES OF *N. glauca*

Knopp solution supplemented with :		
No addition	EDTA ( $6.4 \times 10^{-4}$ M)	FUDR ( $7.6 \times 10^{-4}$ M)
0	35	41

These results clearly indicate that FUDR, like EDTA, enabled TMV to replicate in tomato root tips, contrary to what happened in control plants. It remains to be established what relations exist between the phenomenon described by Crowley and Hanson<sup>1</sup>, who used EDTA, and that described here. While the action of EDTA on fostering TMV replication in meristematic tissue may be explained on a microsomal level, as microsomal RNA is used for TMV-RNA synthesis<sup>7</sup>, it is equally plausible to speculate that this compound acts by disorganizing chromosomal structure and function; indeed, EDTA has been shown to cause chromosomal aberrations<sup>8</sup> and to increase the frequency of crossing-over<sup>9</sup>. On the other hand, the action of FUDR could be clearly visualized on the chromosomal level, as its action is rather specific and as it is able to induce chromosomal lesions in plants<sup>10</sup>. Thus the possibility exists that a general weakening of the controlling system in the cellular machinery permits virus biosynthesis in cells normally resistant to virus invasion.

## GENETICS

### Localization of Haptoglobin and ABO

RECENTLY, P. S. Gerald *et al.*<sup>1</sup> published their observations on haptoglobin (Hp) in a family with a child in which one of the D group chromosomes (13, 14 or 15) was deformed into a ring structure, which implies that part of the chromosomal material of the chromosome is deleted. It appeared that the carrier of this chromosome lacked the Hp genetical contribution from her father (father, Hp 2-2; mother, Hp 2-1; carrier child, Hp 1-1). Therefore the authors tentatively proposed that the haptoglobin locus is on the end of the long arm of a D chromosome. We had the opportunity to study a number of families with translocations, and our preliminary results are presented as additional information on the localization of Hp.

Family K. with D-D translocation, studied in the University Laboratory of Genetics in Nijmegen, provided the following information: both parents are heterozygous,

*Hp* 2-1; two out of their seven children are chromosomally normal, *Hp* 2-2; two are carriers of the translocation, *Hp* 1-1; three are heterozygous for *Hp*.

The pedigree of family R-v. d. P. with *D*-21 translocation, also analysed in Nijmegen, contains three brothers: one with the translocation, *Hp* 2-1; one carrier of the translocation, *Hp* 2-2; one normal, *Hp* 2-1. The first of these brothers has seven living children (mother, *Hp* 2-2): four carriers of the translocation, *Hp* 2-2; one carrier, *Hp* 2-1; one non-carrier, *Hp* 2-1; one non-carrier, *Hp* 2-2. This makes a total of 5 non-cross-overs and 2 cross-overs.

Family V. with *D*-21 translocation, studied in the Institute of Human Biology in Amsterdam, consists of the normal father, *Hp* 2-2; the carrier mother, *Hp* 2-1; one normal carrier child and two translocation mongrels, all three *Hp* 2-1.

Combination of the foregoing data amounts to 10 non-cross-overs: 2 cross-overs; this ratio has a chance probability of  $79/4096 = 0.019$ . The observed crossing-over rate is  $2/14 = 0.14$ .

Some further information can be found in publications by Hamerton *et al.*<sup>1</sup> (*D*-*D* translocation; 4 non-cross-overs: 1 cross-over), and by Macintyre *et al.*<sup>2</sup> (*D*-21 translocations; 2 non-cross-overs).

Combination of these results with ours does not change the crossing-over frequency (in total  $12 : 2 + 6 : 1 = 18$  non-cross-overs : 3 cross-overs = 14 per cent crossing-over).

Since a crossing-over frequency of only 14 per cent is very unlikely to occur if the *Hp* locus is situated on the end of the long arm of the *D* chromosome, it seems reasonable to think of a localization on the short arm.

The R-v. d. P. family gives also additional information on the still undecided problem of localization of ABO on chromosome 21. A genotype *A*<sub>1</sub>*O* carrier of the translocation married to a normal group *O* woman has five carrier group *O* children, one non-carrier group *A*<sub>1</sub> and one non-carrier group *O*. Other families in the pedigree indicate the translocation to be associated with the *O* gene of the ABO system. The resulting linkage information is therefore 6 non-cross-overs : 1 cross-over. The chance probability of this ratio is  $8/128 = 0.0625$ .

We thank Dr. H. K. Prins for carrying out the *Hp* typing, and Dr. J. v. d. Bosch for his advice. This work was supported in part by a grant to one of us (L. E. N.) from the U.S. National Institutes of Health (NB 04321-03).

## Chromosomes of the Sperm Whale

THIS report describes the results of a chromosomal analysis of the sperm whale by the method of leucocyte tissue culture. During July and August, 1964, fresh sterile blood was obtained at sea for various research purposes from sperm, finback, and sei whales (*Physeter catodon*, *Balaenoptera physalus* and *B. borealis*, respectively) during the course of commercial whaling operations. The method of blood collection, developed by one of us (R. P. A.), will be described elsewhere.

Using this system, blood was collected, aseptically, in heparin, within 10 min of cessation of respiration, from a 56-ft. male sperm whale captured at 2.45 p.m. on August 20, 1964, in lat. 65° 20' N., long. 30° 10' W.

Peripheral blood leucocytes were grown in tissue culture by a modification of the method of Moorehead *et al.*<sup>1</sup>, using a medium composed of 80 per cent Eagle's minimum essential medium, 20 per cent autologous serum, phytohaemagglutinin and antibiotics.

The distribution of chromosome numbers in twelve suitable metaphase spreads showed a mode of 42 chromosomes:

Number of chromosomes	38	39	40	41	42
Number of cells counted	1	1	2	0	8

A karyotype constructed from one well-spread cell containing the modal number and an intact cytoplasmic halo (Fig. 1) showed fourteen metacentric or submetacentric chromosome pairs, six subacrocentric pairs, and two chromosomes, one a large metacentric, the other a small submetacentric or subacrocentric with uneven short arms, which could not definitely be paired. In the absence of a female karyotype it is not possible to decide which are autosomes and which are sex chromosomes.

Fig. 1. Metaphase spread and karyotype from peripheral blood leucocytes of male sperm whale (*Physeter catodon*).

The relatively low diploid number and the predominance of metacentric with absence of acrocentric chromosomes is interesting in view of suggestions, made by various authors<sup>2-4</sup>, that evolutionary specialization is associated with reciprocal translocation between acrocentric pairs and a balanced reduction in diploid number (Robertsonian-type variation<sup>5</sup>). Such a process would be likely to occur in a group of mammals as highly specialized as the Cetacea.

Since this communication was prepared for publication Cortman and Richart<sup>6</sup> have described the chromosomes of a male ring seal, *Phoca hispida krascheninikovi*, in which a similar reduction in diploid number and tendency to metacentricity was found.

We thank Mr. Loftur Bjarnason, Manager of Nvalur, H. F. (Whale, Ltd.), Captain Jonas Sigurdsson, his crew, and other members of this whaling company, and Dr. Pall Palsson, director of the Institute for Experimental Pathology, University of Iceland School of Medicine, for making this work possible. We thank Mr. Gerald Rogell, Mrs. Phyllis Robinson, and Miss Katharina Lorient for their help.

## Brilliant Cresyl Blue as a Stain for Plant Chromosomes

THE usefulness of cresyl violet as a stain for rapid preparations of root tip squashes has been recently reported<sup>1</sup>.

For the past two years I have used the related stain brilliant cresyl blue in aqueous solution, in preference to conventional staining procedures which have generally been more time-consuming. More than forty species of flowering plants have been tested with aqueous brilliant cresyl blue without any difficulties being encountered.

In Amirkhanian's method<sup>1</sup>, cresyl violet was dissolved in 50 per cent acetic acid. This solvent proved unsuitable with brilliant cresyl blue which was finally prepared as a 10<sup>-4</sup> M solution in distilled water.

Consequently the same solution of brilliant cresyl blue may be used with vital staining of dividing nuclei as well as with normal fixation procedures. It is thus possible to compare fixed and living chromosomes (or other cellular components) which may be an important consideration in some cytological studies.

Brilliant cresyl blue is classified as a quinone-imine dye belonging to the sub-group of oxazines. According to Conn<sup>2</sup> "they are not stains having very general application". The dye marketed under the name of cresyl violet is of uncertain chemical structure, but is probably closely related to cresyl violet acetate, the formula of which has been characterized from the chemical synthesis of the material. Since the chemical formula of brilliant cresyl blue is definitely known, it would be preferable to use this dye in place of cresyl violet in cytological studies where a knowledge of the underlying histochemical reactions is desirable.

In squash preparations involving refractory material (for example, shoot and root meristems of grasses) brilliant cresyl blue gives good results after pectinase treatment<sup>3</sup>. It is also compatible with colchicine and other chemicals used in pre-treatment<sup>4</sup>.

The procedure in squashing is as follows: After pre-treatment (if any) root tips or other meristematic tissues are fixed in aceto-alcohol (1 part glacial acetic acid : 3 parts ethanol). Other appropriate fixatives may be used<sup>4</sup>.

After fixation, the specimen is hydrolysed in 1 N HCl for 5 min or longer at 60° C and transferred to a drop of brilliant cresyl blue on a slide (a 10<sup>-4</sup> M solution in distilled water, or stronger solutions up to 10<sup>-3</sup> M). The specimen is teased out, tapped and squashed under the coverslip in the usual way<sup>4</sup>. By warming the slide gently over a spirit lamp the cytoplasm may be cleared to the degree desired. Permanent preparations may be made by inverting the slide in 80 per cent ethanol in a smearing dish, dehydrating rapidly in 100 per cent ethanol, and mounting in 'Euparal' or Gurr's neutral mounting medium. Other methods of making the preparation permanent may equally well be applied<sup>4</sup>.

Brilliant cresyl blue in dilute aqueous solution provides the means for rapid squash preparations and is applicable to a wide range of different species of flowering plants and, if required, the concomitant metachromatic staining of living cells<sup>5</sup>.

An aspect of added interest is the report of retardation of the growth of tumours by brilliant cresyl blue<sup>6</sup>; further work with this dye might throw valuable light on the course of cell division, not only in cancerous growths but also in normal tissues.

## VETERINARY SCIENCE

### Restricted Protein Intake and Avian Atherosclerosis

ALTHOUGH low-protein diets in the presence or absence of supplementary dietary cholesterol give rise to a marked hypercholesterolaemia in Leghorn cocks, nevertheless, we observed<sup>1,2</sup> a reduction in the severity of abdominal atherosclerosis after 10 or 20 weeks on the experimental low-protein diets. We have examined the effects of prolonged restrictions (20 months) of protein intake in relation to plasma cholesterol, body composition and abdominal aortic and coronary atherosclerosis.

Day-old Leghorn cocks from the same random-bred strain used in previous investigations of avian atherosclerosis<sup>3,4</sup> were divided into two groups of sixty, one being given an adequate and the other an inadequate protein-level. The basic diet was composed of soy-bean meal, glucose, maize oil, vitamins and minerals. Its protein content was continuously diminished with increasing age and the average daily intake per bird throughout the experiment is listed in Table 1.

Mortality was 31 and 25 birds from the adequate and inadequate protein-intake groups, respectively. During the course of the examination another 14 and 20 cocks from each group were removed for nitrogen metabolism studies. Blood was taken from the 15 survivors in each group for plasma-cholesterol analysis prior to the termination of the experiment. The birds were killed with chloroform, and the liver and aorta removed for further analysis. Liver cholesterol was determined<sup>5</sup> on a portion of the lipid extracted with chloroform-methanol (2:1). The aorta was macroscopically graded<sup>4</sup> on a scale of 1-3 and then examined and graded histologically<sup>4</sup>, as were also the

Table 1. COMPARISON BETWEEN SEVERITY OF ACETIC AND CORONARY ATHEROSCLEROTIC LESIONS IN LEGHORN COCKS ON NORMAL OR RESTRICTED LEVELS OF DIETARY PROTEIN OVER A PERIOD OF 20 MONTHS

Measurements	Protein Intake Normal	Restricted

\* For nitrogen metabolism investigations.

† Mean value with its standard error.

coronary arteries. The remainder of the carcass, devoid of aorta and liver, was dried, and nitrogen and extractable lipid determined<sup>8</sup>.

All the results are given in Table 1. The protein intake of the restricted group was approximately 60 per cent of that of the normal group. This was reflected in a significantly lower body-weight at the end of the 20-month experimental period. There was no difference between the two groups, however, in the percentages of body nitrogen and extractable lipid.

As in our previous studies<sup>1,2</sup>, there was a significantly higher plasma cholesterol concentration in the group of cocks on the restricted protein intake. This difference was not reflected in differences in liver cholesterol values. There was no difference in aortic atherosclerosis as judged by either macroscopic or histological scoring. The coronary arteries, however, showed markedly greater severity of atherosclerosis for the cocks on the normal protein intake in comparison with those on the restricted intake. These observations lend further emphasis<sup>4,5</sup> to the poor correlation between cholesterol values and the incidence and severity of atherosclerosis.

In contrast to the present observations, Stamler *et al.*<sup>6</sup> observed an increased incidence of lesions with low-protein diets; their data indicate, however, that the protein-level considered 'low' was adequate for normal growth as judged by a comparison of the final weights of the 'low' and high-protein groups.

In the fowl, spontaneous coronary atherosclerotic lesions do not develop in parallel with, and are generally less severe than, those of the abdominal aorta<sup>7</sup>. It may be that in the fowl, as in man, where the coronary arteries and the aorta are often affected to different degrees by atherosclerosis, these two sites react differently to atherogenic stimuli. This may be why less-severe coronary lesions were observed in birds after a restricted protein intake while no difference was seen in the aortic lesions.

This work was supported in part by grants from the U.S. Public Health Service and the Sussex and Monmouth County Heart Associations.

### Premature Delivery and Survival in Lambs

BETWEEN 105–110 days gestational age (term is about 147 days) it is impossible to obtain independent survival of lambs delivered by Caesarean section, even on ventilation with 100 per cent oxygen<sup>1</sup>. This estimate of the ultimate limit of viability in sheep agrees well with the histological changes which begin in the lungs at about 90 days gestation<sup>2</sup>. The lamb is very mature at birth, so there was every reason to suppose that most lambs delivered prematurely would survive. However, 23 Clun-Hampshire lambs survived after being delivered (by Caesarean section under local or epidural anaesthesia) at 142 days gestation or more, whereas 4 of 23 that were delivered at 138–141 days gestation did not survive. The weights of these 4 lambs were 3.3–4.2 kg and they all appeared well developed. But they failed to maintain spontaneous breathing for more than a few minutes after the umbilical

cord was tied, in spite of prolonged efforts at resuscitation by positive pressure ventilation with oxygen.

This large mortality rate was surprising, because 138 days represents 94 per cent of normal term in sheep, and one expects that all infants should establish normal respiration on premature delivery after only 90 per cent of term in man or rhesus monkeys, when instances of gross anomalies and disease are excluded. However, the numbers involved were small and therefore enquiries have been made into the losses of newborn lambs in flocks where accurate records of tupping dates were available.

The causes of perinatal wastage in lambs under field conditions are various. Hence, in examining that portion of the perinatal mortality rate which may fairly be attributed to temporal prematurity, certain criteria must be met. The data presented below refer only to sheep in supervised recorded flocks with individual mating dates and a high standard of antenatal care under competent daily inspection; the flocks have been free for at least 5 years from any clinical evidence of contagious illness known to affect pregnancy; the pregnancies were uncomplicated and lasted more than 90 per cent of the normal gestation length (132–135 days), and with normal parturition yielding lambs free of physical defects and of minimal viable birth weights (2.75 kg for males and 2.25 kg for females of the breeds concerned); they include cases only of recent stillbirth, death during parturition, and death in the first 24 h after birth.

Data meeting these criteria have been assembled for 1,077 pregnancies during 1960–64 in four flocks of two pure breeds, breed A being similar to the Clun-Hampshire and breed B being somewhat smaller. The mean gestation length of breed A is said to be 147 days and our figures endorse this estimate; that for breed B is thought to be longer and may be 149–150 days, with which our limited data concur.

For preliminary study over some years we have accepted a variation of 5 per cent about the mean gestation length as the normal range, that is, 144–150 days in breed A and 146–154 days in breed B. A lamb born after a gestation shorter than this is considered premature, a 2.5 per cent shortening being considered slight temporal prematurity (141–143 days for breed A and 144–146 days for breed B) while a gestation only 95–90 per cent of the mean was considered as marked temporal prematurity in the lambs.

Table 1. EFFECTS OF PREMATURE DELIVERY ON SURVIVAL IN SHEEP

	Breed and flock				
	A8	A20	A53	Total A	B2
Delivered at term $\pm 2.5\%$ :					
Mean gestation age (days)	147.2	147.0	147.6	147.3	149.8
Average litter size	1.81	1.87	1.87	1.86	1.51
No. lambs	261	1,181	389	1,731	226
Deaths	27	107	53	167	26
% dead	10.3	9.5	9.7	9.7	11.5
Delivered at term less 2.5–5%:					
Average litter size	1.67	1.87	1.73	1.80	1.61
No. lambs	10	28	14	52	21
Deaths	2	6	5	13	12
% dead	20	21	36	25	57
Delivered at term less 5–10%:					
Average litter size	—	1.8	2	1.8	1.5
No. lambs	—	9	2	11	3
Deaths	—	8	2	10	2

<sup>2</sup> Tests on the total data from breed A show that there is a significant association between survival at birth and maturity ( $P < 0.001$ ).

Table 1 shows that for similar average litter sizes, the perinatal mortality rises from about 10 per cent for full-term lambs to 25 per cent or more for slightly premature lambs, and even higher for markedly premature lambs. Hence lambs of gestational age less than 95 per cent of the normal, that is, of 5 per cent prematurity, are not of normal viability. In this respect the lamb appears to differ from man, rhesus monkey and cattle. The mortality rate on delivery at term also compares very unfavourably with that in man.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

**SENIOR RESEARCH ASSOCIATE** (with an honours degree in soil science or equivalent, preferably with some postgraduate experience) in the DEPARTMENT OF SOIL SCIENCE for work in connection with a landscape reclamation research project—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, 2 (July 24).

**RESEARCH WORKER IN INDUSTRIAL SOCIOLOGY** in the DEPARTMENT OF SOCIAL SCIENCE—The Registrar, The University, Liverpool, quoting Ref. OV/186 (July 28).

**STAFF TUTOR IN PSYCHOLOGY** in the DEPARTMENT OF ADULT EDUCATION AND EXTRA-MURAL STUDIES, to conduct courses principally for voluntary and professional workers, and other professionally engaged students—The Registrar, The University, Liverpool, quoting Ref. OV/184 (July 28).

**TUTORIAL ASSISTANTS (2)** (recent graduates with qualifications in sociology, social anthropology or in a related discipline) in the DEPARTMENT OF SOCIOLOGY AND SOCIAL ANTHROPOLOGY, to help in the teaching of sociology—The Registrar, The University, Hull (July 28).

**DEMONSTRATOR (Hydrology)** in the DEPARTMENT OF FORESTRY AND NATURAL RESOURCES, to assist in the teaching of the hydrological aspects of land-use ecology, and to pursue research studies in a field of hydrology related to rural land use—The Secretary, The University, Edinburgh (July 28).

**DEMONSTRATOR** (with, or taking, an honours degree in botany and, either have studied, or have an interest in, bacteriology or microbiology) in the DEPARTMENT OF BOTANY—The Registrar, The University, Nottingham (July 30).

**GALLAHUE FELLOW** in the DEPARTMENT OF MYCOLOGY AND PLANT PATHOLOGY to carry out research on the microbiology of tobacco, and will have opportunities for discussing research problems and co-operation with the personnel of the Gallahue factories in Northern Ireland—The Deputy Secretary, Academic Council, The Queen's University of Belfast, Belfast, 7, Northern Ireland (July 31).

**LECTURER** (with a good honours degree and/or a higher degree in psychology, and preferably experience in remedial education) in the DEPARTMENT OF PSYCHOLOGY—The Registrar, University College of North Wales, Bangor, North Wales (July 31).

**LECTURER OR ASSISTANT LECTURER** in the DEPARTMENT OF PURE MATHEMATICS—The Registrar, University College of Wales, Aberystwyth (July 31).

**RESEARCH ASSISTANT** in the DEPARTMENT OF PHYSICS for work on plasma heating by lasers—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (July 31).

**RESEARCH FELLOW OR RESEARCH ASSISTANT** (with an honours degree in psychology) in the DEPARTMENT OF PSYCHOLOGY, to work in a small team sponsored by the M.R.C. to study various aspects of attention in normal and abnormal subjects—A. B. Burnell, Department of Psychology, University of Aberdeen, Taylor Building, Old Aberdeen, Scotland (July 31).

**RESEARCH OFFICER** (with a pass degree, H.N.C., H.N.D. or equivalent, and experience of crystal growth or metallurgy) in PHYSICS—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (July 31).

**SENIOR LECTURER** in the DEPARTMENT OF PSYCHIATRY—The Secretary, The University, Edinburgh (July 31).

**ASSISTANT LECTURER** in BOTANY—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (August 2).

**RESEARCH ASSISTANTS (2)** (honours graduates in sociology, physiology or anatomy) with the NEUROLOGICAL RESEARCH GROUP in the DEPARTMENT OF SOCIOLOGY, to work with Prof. D. Barker on problems connected with the innervation of vertebrate skeletal muscle, for example, investigations into the process of motor end-plate replacement—The Secretary, University of Durham, Old Elvet Hall, Durham (August 2).

**L.B.M. RESEARCH FELLOW** in the DEPARTMENT OF PSYCHOLOGY, to carry out research into the stimulation of the retrieval of linguistic information by the brain, and will be responsible for the programming of the stimulation studies—The Registrar, The University, Sheffield (August 9).

**PROFESSOR OF SOCIOLOGY** in the SCHOOL OF HUMANITIES AND SOCIAL SCIENCES—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7 quoting Ref. CST 65/62 (August 9).

**CHAIR OF CONTROL ENGINEERING** (candidates may have interests in any branch of control engineering—The Deputy Secretary, The University, Southampton (August 14).

**LECTURER IN BIOLOGICAL CHEMISTRY**—The Registrar, The University, Manchester, 13, quoting Ref. 140/65 (August 14).

**LECTURER** (with medical qualifications registrable in the United Kingdom) in MEDICINE—The Registrar, The University, Manchester, 13, quoting Ref. 146/65 (August 14).

**POST-DOCTORAL ASSISTANT (Chemist)** in the DEPARTMENTS OF CHEMISTRY AND BIOCHEMISTRY for work on the effects of radiations on polymers of biological importance, under the immediate direction of Dr. G. O. Phillips—Prof. K. S. Dodgson, Department of Biochemistry, University College of South Wales and Monmouthshire, St. Andrew's Place, Cardiff (August 14).

**RESEARCH ASSISTANT** in the DEPARTMENT OF BIOCHEMISTRY—Prof. K. S. Dodgson, Department of Biochemistry, University College of South Wales and Monmouthshire, St. Andrew's Place, Cardiff (August 14).

**RESEARCH ASSISTANT** (with a good knowledge of mathematics, preferably at the university level, and typing and general secretarial experience) for the *Journal of Applied Probability*—The Registrar, The University, Sheffield, 10 (August 14).

**UNIVERSITY LECTURER IN THEORETICAL CHEMISTRY**—Prof. R. H. Richards, F.R.S., Physical Chemistry Laboratory, The University, South Parks Road, Oxford (August 14).

**LECTURER** (with experience of electrical machine design, operation or control) in ELECTRICAL ENGINEERING—The Registrar, University College of Swansea, Singleton Park, Swansea (August 15).

**SENIOR LECTURER** in PHARMACOLOGY in the DEPARTMENT OF MATERIA MEDICA AND THERAPEUTICS—The Secretary, The University, Aberdeen (August 21).

**POST-DOCTORAL RESEARCH FELLOW** in ORGANIC CHEMISTRY—The Registrar, The University, Hull (August 28).

**RESEARCH ASSISTANT** (preferably with experience in geology and/or microprobe analysis) in the DEPARTMENT OF GEOLOGY AND MINERALOGY to be concerned with electron probe microanalysis—The Reader in Mineralogy, Department of Geology and Mineralogy, University of Oxford, Parks Road, Oxford (August 28).

**LECTURER** (with the ability to lecture in physics) in the SUB-DEPARTMENT OF GEOPHYSICS—The Registrar, The University, Liverpool, quoting Ref. OV/182 (August 30).

**JUNIOR LECTURER/LECTURER** in PHILOSOPHY at Rhodes University, Grahamstown, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 31).

**LECTURER** (preferably with some experience of hospital laboratory work, particularly in a biochemical department) in the DEPARTMENT OF CLINICAL CHEMISTRY—The Secretary, The University, Edinburgh (August 31).

**LIBRARIAN** at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, August 31).

**SENIOR LECTURER/LECTURER** (preferably with a knowledge of, and special interest in, bacteriology) in MICROBIOLOGY at Rhodes University, Grahamstown, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 31).

**EXECUTIVE DEAN** (with medical qualifications, and also academic and administrative experience) of the FACULTY OF MEDICINE—The Secretary, The University, Edinburgh (September 7).

**CHAIR OF PHILOSOPHY** at the University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 18).

**ADMINISTRATIVE ASSISTANT** (with a university degree or equivalent qualification, and preferably not more than 30 years of age) in the DEPARTMENT OF AERONAUTICAL AND AUTOMOBILE ENGINEERING—The Registrar, Loughborough College of Technology, Loughborough, Leicestershire.

**ANIMAL NUTRITIONIST** (national of the United Kingdom or the Republic of Ireland, with a degree in agriculture and postgraduate training or experience in biochemistry of agricultural biochemistry) with the East African Agriculture and Forestry Research Organization, to investigate metabolism of tropical and temperate type cattle with a tropical environment—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. R.O. 213/214/016.

**ASSISTANT CONSERVATORS OF FORESTS** (nationals of the United Kingdom or the Republic of Ireland, between 30 and 40 years, with a degree in forestry or a degree in natural science plus a diploma in forestry) in Tanzania (Tanganyika and Zanzibar), for the administration of normal Districts, including reservations, surveys, enumerations, supervising and directing of harvesting and advice to local authorities on forestry matters—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. R.O. 324/173/01.

**BIOCHEMIST**—The Medical Superintendent, Maryfield Hospital, Dundee, Scotland.

**CHAIR OF CHEMISTRY** (preferably candidate who has specialised interests in organic chemistry or in biological chemistry)—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 29/6.

**HONOURS GRADUATES (first- or second-class) in the MECHANICAL ENGINEERING DEPARTMENT**, to undertake directed research in the field of turbine blade vibration—The Head of the Department of Mechanical Engineering, Battersea College of Technology, London, S.W.11, quoting Ref. D 18.

**LECTURER** (with teaching interests in stereo-chemistry and physical organic chemistry) in ORGANIC CHEMISTRY to assume responsibility for the organisation and development of teaching of the subject in the Department—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting Ref. CST 65/61.

**LECTURER OR ASSISTANT LECTURER** (preferably with interests in (i) numerical analysis or computer science; (ii) fluid dynamics or any other branch of continuum mechanics) in APPLIED MATHEMATICS—The Registrar (Room 22, O.B.B.), The University, Reading.

**MASTER** to teach Mathematics to scholarship level—The Headmaster, Monkton Combe School, near Bath.

**PHYSICIST, MECHANICAL OR MECHANICAL ENGINEER, or METEOROLOGIST** (recently graduated) in the BUILDING CLIMATOLOGY RESEARCH UNIT, DEPARTMENT OF BUILDING SCIENCE, to assist in investigations of the characteristics of turbulence in the natural wind—The Registrar, The University, Liverpool, quoting Ref. 176/N.

**POST-DOCTORAL ASSISTANTS; TUTORIAL ASSISTANTS; and RESEARCH SCHOLARS** (graduates or holders of an equivalent qualification) in CHEMISTRY—The Secretary, Department of Chemistry, St. Salvator's College (University of St. Andrews), St. Andrews, Fife, Scotland.

**RESEARCH ASSISTANT** (with a first degree in physics, chemistry, ceramics or metallurgy) in the COLLEGE OF CERAMICS, for work on an interesting sponsored research project relating to the sintering of alumina—The Clerk to the Governors, North Staffordshire College of Technology, Stoke-on-Trent, Staffordshire.

**RESEARCH FELLOW, RESEARCH ASSISTANT and a RESEARCH STUDENT** at the Tidal Institute and Observatory, to participate in a three year research project to study the generation, propagation and methods of forecasting storm surges and related tidal phenomena in the North Sea and adjacent areas—The Registrar, The University, Liverpool, quoting Ref. OV/184.

**RESEARCH STUDENTS and POST-DOCTORAL WORKERS** in the DEPARTMENT OF MICROBIOLOGY for studies of microbial chemistry in relation to pathogenicity and immunity—Prof. H. Smith, The University, Edgbaston, Birmingham, 15.

**SENIOR TECHNICIAN** (experienced in the major biochemical techniques including enzymology, radioisotopes, biochemical fractionation and animal care, and preferably experience both in supervising a teaching laboratory and in research) to take charge of an advanced biochemistry laboratory course—Department of Biochemistry, University of British Columbia, Vancouver 8, Canada.

**SENIOR TECHNICIAN** (with a good knowledge of laboratory procedure and holding I.S.T. or I.M.L.T. qualifications) to assist with general laboratory duties and research in a University Department—The Regius Professor of Medicine, Radcliffe Infirmary, Oxford.

**TECHNICAL ASSISTANT** (preferably with previous experience) in the RADIOLOGICAL MICROSCOPE UNIT—Prof. H. J. J. Blackwood, Royal Dental Hospital, 32 Leicester Square, London, W.C.2.

## ORGANIZATION OF BUILDING RESEARCH

THE Trend Committee in its report on the organization of civil science had some reservations about the future position of the Building Research Station and suggested that some consideration should be given to its transfer to the Ministry of Public Building and Works. Such a proposal has been strongly questioned, however, and in the meantime, with the disappearance of the Department of Scientific and Industrial Research, under the Science and Technology Act, the Building Research Station has been transferred to the Ministry of Technology. Discussion on this point alone would give special interest to Dr. M. S. Kaplan's Unwin Memorial Lecture to the Institution of Civil Engineers, on the pattern of building and civil engineering research in Britain last April. Dr. Kaplan, however, surveyed a much wider field and began by pointing out that present-day expenditure on building and civil engineering in Britain has been estimated at more than £3,000 million. Of this about £2,000 million is being spent on new works, and £1,000 million on maintenance. The industry employs some 1.5 million people, or about 6 per cent of the working population.

In a review of Government institutions concerned directly or indirectly with research, two points stand out. The Chief Scientific Adviser's Division of the Ministry of Works, set up in 1944, was transferred to the Department of Scientific and Industrial Research in April 1950, and the Ministry's own Advisory Council on Building Research and Development, which was established in 1947, was disbanded in 1959 and its responsibility passed to the Building Research Board. Only in 1962 was there established a Directorate-General of Research and Development at the Ministry of Public Building and Works with four directorates: (1) of development, to promote new and more efficient ways of building; (2) of building management, to improve management techniques and more effective co-ordination throughout the building process; (3) of research and information, to formulate research needs in conjunction with the industry and the professions, to improve the technical information services and to examine the pattern of education in the construction industries and promoting movements; (4) of economic intelligence, to collect, interpret and disseminate statistical and economic information. Since then, in March 1964, the Government has established the National Building Agency to help the industry to deal with the great upsurge of demand now facing it and to encourage methods of increasing productivity, both in traditional and industrial building. The Agency is financed by the Government but is independent of direct Government control.

The Agency is aware of the dangers of duplication and overlapping, and works in close liaison with various Government departments and inter-departmental working parties to avoid these difficulties. Dr. Kaplan points out that it is not at all clear how the activities of the Association and of the Director-General of Research and Development and of the Building Research Station will develop in relation to each other. He believes that there is a danger of overlapping functions which could be serious because

of the shortage of qualified people. More serious, however, is the need to make a much greater use of the universities. The need for more university research in this field is two-fold. First, a greatly expanded effort in building and civil engineering research will call for many more architects, engineers and others with training in research: at present the number of research students in this field is very small. Secondly, he emphasizes that building and civil engineering should make much more use of the expertise and knowledge of university teachers, and doubts whether full advantage can be taken of the research facilities and skills available in British universities on the 'stop and go' basis which now exists. The establishment of more research units like the Pilkington Research Unit at the University of Liverpool, which is studying environmental requirements of buildings, and the Hospital Engineering Research Unit at the University of Glasgow, may well be the answer.

While there were several Research Associations carrying out research of interest to the construction industry, particularly as regards constructional materials, and others dealing with heating and ventilating, welding, water and hydro-mechanics, the Civil Engineering Research Council was established in November 1960, and Dr. Kaplan was invited to become its first director of research. Following an application to the Department of Scientific and Industrial Research the Civil Engineering Research Council had been offered a grant for an initial period of three years from January 1, 1963. This was conditional on the Council raising an annual income of not less than £40,000, when the Department would make a pound-per-pound grant up to £80,000 per annum. It was agreed to adopt a constitution based on the model for the Research Associations, and the Civil Engineering Research Association came into being on February 3, 1964, taking over the activities of the Civil Engineering Research Council. At present the Research Association is without laboratories of its own, and is using facilities provided by Government research establishments, other research associations, the universities and industry. Besides identifying research projects the Association receives and considers proposals for research from professional institutions, universities, consulting engineers, contractors, suppliers of materials, Government departments and other organizations connected with the industry. Technical advisory panels have been formed, covering particular aspects of civil engineering. The function of these panels is to examine proposals for research and to consider reports on research in progress. Not the least valuable result of the panels' work is that they help research workers and others to become more aware of the research needs of the industry. The income of £158,000 for 1964 exceeded the target figure for that year by more than £38,000, and some 50 approved research projects are being carried out at the Building Research Station, the Road Research Laboratory, and the Hydraulics Research Station, by the Cement and Concrete Association, and in the universities and laboratories of other Research Associations. Dr. Kaplan, however, emphasizes the importance

of disseminating as rapidly and effectively as possible the results of research; shortcomings in this respect could be as serious as shortcomings in the prosecution of research itself. He also recognizes, however, that the construction industry and associated professions must be prepared to study and make use of the results of research.

Dr. Kaplan does not regard the present scale of building and civil engineering research as satisfactory. No reliable and comprehensive information exists at present, but he states that the survey now being carried out by the Ministry of Public Building and Works covers more than two thousand organizations and reveals the existence of more than eight hundred research and development bodies. In May 1962 the Minister of Public Building and Works, Mr. G. Rippon, suggested to the building industry the establishment of a Building Research and Information Association, to be managed and financed jointly by industry and Government. While the Government was willing to play its part in increasing the total effort in this field, Mr. Rippon believed that successful results could not be obtained unless the industry itself played a greater part in both fields of activity. Accordingly, his proposal was that the Government should contribute up to £150,000 a year for three years, if the industry matched this contribution, and conditional on a minimum contribution from the industry of £50,000 per year. It was hoped that the Association's budget would build up to at least £500,000 in five years. In September 1963 the Minister met a deputation of organizations and professions in the building and associated industries to discuss the proposal, which was accepted in principle. It was agreed to set up a working party with Mr. D. Woodbine-Parish as chairman to examine research and information services, the scope of any association to achieve improvements, its constitution and the arrangements for financing it. The working party reported to the Minister in December 1963, but found little support from the industry for the suggestion that a Development Council should be established with the right to impose a statutory levy for research and information.

This working party attempted to assess the scale of research and development and concluded that, excluding the production of materials and components, the annual expenditure on research and development advisory services was about £3 million a year, or 0.2 per cent of the net output of the industry. It was difficult to find a comparable figure for research and development on materials and components used in construction, the annual output of which is estimated at about a further £150 million a year. Annual expenditure on research in the glass, cement and ceramics (including refractories) industries is about £2 million, and in the absence of any sufficient analysis of expenditure in the metals, plastics, paint, and other materials which contribute to construction, the working party suggested that the relevant figure was of the order of £5 million, which would put the total expenditure on research and development for the construction industry and its suppliers at about £10 million a year, or 0.3 per cent of the estimated annual output of about £3,000 million. This supported the opinion of the Advisory Council of Scientific Policy in its report for 1959-60 that expenditure on research in this industry compares unfavourably with that in other industries. At a meeting in July 1964, Mr. Rippon proposed the establishment of a Construction Industry Research and Information Commission, broadly on the lines which had been suggested in the Woodbine-Parish Report. This Commission

would be appointed by the Minister after consultation with the industry, with the main functions of surveying the industry's research and information needs and capacity, advising the Minister on the income to be raised by levy and apportioning the financial resources between the proposed Building Research and Information Association, the Civil Engineering Research Council, and other relevant research organizations. A first task of the Commission would be to advise on a statutory levy on the industry. At this meeting Sir Herbert Manzoni, chairman of the Civil Engineering Research Association, submitted proposals on behalf of the Federation of Civil Engineering Contractors, the Association of Consulting Engineers and the Institution of Civil Engineers. These proposals indicated that further developments should be primarily based on the industry, and informal discussions had revealed the possibility of establishing one research association to cover both building and civil engineering. The Minister agreed to consider these proposals and a further memorandum was submitted by Sir Herbert Manzoni in September 1964, suggesting the establishment of a Building and Civil Engineering Research Association, financed jointly by Government and industry.

In view of the General Election and change in Government, discussions with the new Minister, Mr. C. Pannell, were delayed until December 1964, and as a result of further discussions, proposals were submitted to the Minister on March 10, 1965, suggesting that the industry should raise £170,000 in the first year, rising to £250,000 in the third year, to finance the proposed Research Association. A study of detailed arrangements to obtain these funds and assure continuity of support was being made, and it was anticipated that the Government would make a pound-for-pound grant so that the initial annual income of the Association would be about £350,000, rising to some £500,000 in the third year. This Research Association would develop an information and advisory service with a central organization, together with a regional organization spread over England, Scotland and Wales. Dr. Kaplan emphasizes that final decisions on these proposals, which have now been before successive Governments for almost two years, should be reached in the near future. Almost half the total output of the construction industry is paid for by central and local government and other public bodies, for houses, schools, hospitals, roads, power stations, harbours and so on, and the Government responsibility is very clear. He does not agree, however, that research in this field should be entirely financed and controlled by the Government, although at present about 90 per cent of the cost of the Building Research Station is paid for by the Government. He rightly emphasizes that, as the Building Research Board has pointed out, the prime criterion for the selection of research projects should be the need for the knowledge that they are designed to provide rather than the prospects of external financial support. The Building Research Board is obviously concerned that too great an emphasis on obtaining finance from industry might lead to activities being orientated excessively towards immediate needs. Dr. Kaplan seems to doubt whether larger financial contributions towards research at the Building Research Station itself are likely to be forthcoming from the construction industry. He insists that the Building and Civil Engineering Research Association, if established, will require its own experimental facilities, although the building of a further laboratory might not be justified. He suggests that the Minister of Technology should

consider the possibility of the Building Research Station's facilities being jointly financed and controlled by industry and Government under the aegis of the proposed Building and Civil Engineering Research Association. If such arrangements could be worked out they could well be in the best interests of both Government and industry. Examination of the research projects at present being sponsored by the Association shows that most of them are in the national as well as in the industry's interest and that many are of a long-term, basic character. This experience is confirmed by that of the Fire Research Organization, which is operated and financed jointly by the Government and the fire insurance companies. Finally, he points out that the Royal Institute of British Architects supported the establishment of the Building and Civil Engineering Research Association on the understanding that it would not prejudice the setting up later of a Research Council to study the problems of the built environment and covering the whole field of physical planning, architecture and construction. In his Tavistock Lecture for 1964, Lord Holford, in urging the formation of such a Research Council, suggests that it would draw its membership, to begin with, from the existing research organizations in the construction industry and from the associated professions, including those concerned with urban studies and with the use and development of land. It would be related to this whole field of activities just as other Research Councils are to agriculture and medicine and now also natural resources. It should not be divorced from industry and should be connected with all the sciences in which advances are being made affecting our knowledge of what to build and how to build it. He visualized such a Research Council as creating a demand for new thinking at the same time as it encourages and co-ordinates an increasing supply.

Lord Holford recognized that the relations of any such council would need careful definition if it were decided, as the Government has now done, on the recommendation of the Heyworth Committee, to set up a Research Council for the social sciences as a whole. Clearly there could be some overlap, for among the fields in which the Heyworth Committee sees a need for more research are included problems not only of regional development but also of land use, the social effects of different forms of environmental planning and design, and of urban redevelopment to form satisfactory social settings. Nevertheless, Dr. Kaplan questions whether the idea of such a Council, as Lord Holford proposes, is too broad to be practicable. It would certainly seem that its functions would inevitably overlap with those of the Social Science Research Council, now to be established. It might well be that the more limited project of a Building and Civil Engineering Research Association would best meet the present need to stimulate building research and to handle the special difficulties presented by the position of the Building Research Station, provided effective co-ordination is ensured between the various Research Councils and other organizations.

The Heyworth Committee in its report rejected the idea of a separate Research Council for the built environment, but the Government in turn did not consider that the proposal of the Heyworth Committee for a joint board from the Research Councils concerned with urban planning matters would be satisfactory. The question of how best to meet the needs of research in the field of urban planning in the broadest sense is thus still under consideration.

## KEPLER'S WORKS

Johannes Kepler

Gesammelte Werke. Band 8: *Mysterium Cosmographicum*; Editio altera cum notis. De Cometis. *Hyperaspistes*. Pp. 516. Geheftet 56 D.M.; In Halbpergament 65 D.M. Band 9: *Mathematische Schriften*. Pp. 560. 48 D.M. Herausgegeben und bearbeitet von Franz Hammer. (München: C. H. Beck'sche Verlagsbuchhandlung, 1963 and 1960, respectively.)

APART from the importance of his works as a monument to a great man of science who was also deeply involved in the religious and political struggles of his time, Kepler's search for a synthesis of mechanical and aesthetic explanations of Nature, carried out with a rigorous regard for observational and mathematical facts, may arouse a sympathetic response from modern scientific readers accustomed to Eddington and *SU*, as well as from professional historians. While several of his main works have been translated into German, only some rather brief extracts are available in English, and the complete eight-volume edition in the original brought out by Ch. Frisch between 1858 and 1871 is virtually unobtainable outside long-established libraries. The sumptuous and generously annotated modern edition of the *Collected Works* in 22 volumes, begun in the 1930's by Walther von Dyck and Max Casper and continued after their deaths by Franz Hammer, is therefore very welcome. The present volumes are the fourteenth and fifteenth in the series to have appeared; Volumes 13-18, containing the *Letters*, came out between 1945 and 1959.

Volume 8 contains three works from Kepler's late period. The second (1621) edition of the *Mysterium Cosmographicum*, the youthful work in which he had projected his plan of the five regular solids a quarter-century previously, faced Kepler with the problem of presenting a largely obsolete work which nevertheless embodied the inspiration that had led him to his great discoveries and could, in his mind, still have some validity as a rough framework. He published it unchanged, but with the addition of extensive commentaries after each chapter. The *De Cometis Libelli Tres* (1619) includes earlier work inspired by the apparition of Halley's comet in 1607, which could not be published until public interest had been re-awakened by the famous three comets of 1618. The book describes all four comets in detail, giving Kepler's ideas on their orbits, physical nature and augural significance, notably his suggestion that comets travelled at a non-uniform rate along linear trajectories distorted into apparent curves by the orbital motion of the Earth, and his theory of the expulsion of the material of cometary tails by solar radiation pressure. The third work, *Tychonis Brahe Dani Hyperaspistes*, or "Shield-bearer of Tycho Brahe the Dane" (1625), is an undignified polemic against Scipio Chiaramonti, who had written a treatise *Anti-Tycho* attempting to defend Aristotelian cosmology against Tycho Brahe's criticisms, notably his conclusion from parallax measurements that comets are further off than the Moon and that there could be no solid crystal spheres. An appendix, available in English in *The Controversy on the Comets of 1618* (translated by Stillman Drake and C. D. O'Malley, Philadelphia 1960), sets the record straight with regard to the references made to Tycho Brahe and to Kepler himself in this controversy by Grassi and Galileo (who was no admirer of Tycho Brahe and had quoted Chiaramonti with approval in the *Saggiatore*).

The mathematical works in Volume 9 are *Stereometria Doliorum* (1615), *Messeturus Archimedis* (1616), *Chilias Logarithmorum* (1624) and *Supplementum Chiliadis Logarithmorum* (1625). The *Stereometria*, devoted to the Archimedean problem of determining the volumes of solids of revolution and applications to wine-barrels, is a famous landmark in the history of integration; the results are completed, as well as popularized, in the *Messeturus*,

which has the alternative title of *Oesterreichisches Wein-Visioner Buchlein*.

Kepler's appreciation of the significance of logarithms was delayed for several years by the lack of an opportunity to study Napier's *Descriptio* (published in 1614) at leisure. Afterwards he became an enthusiastic advocate of the new method and wrote his two works on logarithms (which should have been a single book but became accidentally separated) for the two-fold purpose of convincing his colleagues by an independent derivation and of computing a new table with 1,000 values of a uniformly changing numerical argument (as opposed to Napier's table of log sine, etc., for a uniformly changing angle) so as to facilitate their use for non-trigonometric calculations. Kepler's logarithms differ slightly from Napier's and are more accurate; this is due to a small computational error by Napier and not to a mathematical difference between the two derivations as is here claimed by the editor, apparently in accordance with Kepler's own opinion. Like Napier's, they have the very inconvenient property that antilog 0 is  $10^7$  instead of 1, although this disadvantage had in the meantime been removed (at Napier's own suggestion) in the development of dekadische logarithms by Henry Briggs and also in the independent derivation of natural logarithms by Jost Bürgi. Kepler's use of his quasi-Napierian logarithms for the Rudolphine tables unnaturally postponed their obsolescence for a century.

The editor's extended commentaries and notes at the end of each volume provide an excellent account of the history and significance of the preceding works and really make them accessible to the modern reader, especially in Volume 9, in which Kepler's mathematical results are expressed in modern notation. The result is a fine piece of thorough, painstaking scholarship and a notable contribution to the history of science.

## DIFFERENTIAL AND INTEGRAL EQUATIONS

### Asymptotic Solutions of Differential Equations and Their Applications

Edited by Calvin H. Wilcox. (Proceedings of a Symposium conducted by the Mathematics Research Center, United States Army, at the University of Wisconsin, Madison, May 4-6, 1964.) Pp. x+249. (New York and London: John Wiley and Sons, Inc., 1964.) 38s.

### Nonlinear Integral Equations

Edited by P. M. Anselone. (Proceedings of an Advanced Seminar conducted by the Mathematics Research Center, United States Army, at the University of Wisconsin, Madison, April 22-24, 1963.) Pp. xii+378. (Madison: University of Wisconsin Press, 1964.) 6.50 dollars.

### Periodic Differential Equations

An Introduction to Mathieu Lamé, and Allied Functions. By F. M. Arscott. (International Series of Monographs in Pure and Applied Mathematics, Vol. 66.) Pp. 284. (Oxford, London and New York: Pergamon Press, 1964.) 60s.

### Operational Calculus based on the Two-sided Laplace Integral

By Balth. van der Pol and H. Brömmer. Pp. xiii+415. (Cambridge: At the University Press, 1964.) 25s.

THAT most differential equations do not possess exact analytical solutions is by no means an unmitigated disaster, since physics often begins where mathematics ends, as demonstrated, for example, by asymptotic approximations in which the dominant term represents a wave or boundary-layer effect which would otherwise be completely obscured. A veritable feast of asymptotic mathematics, dedicated to Prof. R. E. Langer on the occasion of his retirement as first director of the Mathe-

matics Research Center at Wisconsin, has now been prepared as a book by Langer's younger colleague, Prof. Calvin H. Wilcox, utilizing the services of ten leading experts who have contributed as follows: asymptotic expansions for ordinary differential equations, by W. Wasow; solvable related equations pertaining to turning point problems, by H. L. Turrittin; asymptotic methods for the solution of dispersive hyperbolic equations, by R. M. Lewis; asymptotic solutions and indefinite boundary value problems, by R. W. McKelvey; some examples of asymptotic problems in mathematical physics, by C. C. Lin; on the problem of turning points for systems of linear ordinary differential equations of higher orders, by Y. Sibuya; error bounds for asymptotic expansions, by F. W. J. Olver; asymptotic solutions of elastic shell problems, by R. A. Clark; the integral equations of asymptotic theory, by A. Erdélyi; application of Langer's theory of turning points to diffraction problems, by N. D. Kazarinoff. As might be expected, the collection is very heterogeneous, embracing highly specialized reports on present-day research, expository articles of more general interest, and papers concerned with physical applications. The editor would have done well to commission a fairly expansive introduction by some imaginative mathematician capable of drawing all the threads together and stimulating the imagination, for example, on the lines of the American Mathematical Society 1954 lecture by K. O. Friedrichs. Even so, nobody even mildly interested in asymptotics could find this book dispensable. An excellent photograph of Prof. Langer is included.

A somewhat similar collection of articles on *Nonlinear Integral Equations*, originating from an advanced seminar at the same Center, has been prepared by Dr. P. M. Anselone. The contributions are as follows: direct iteration, existence and uniqueness, by A. Wouk; applications of the fixed-point theorem from Russian mathematicians, by A. P. Thielman; equations in partially ordered spaces, by H. F. Bueckner; Newton's method and variations, by R. H. Moore; on nonlinear integral equations of the Hammerstein type, by O. L. Dolph and G. J. Minty; variational methods for nonlinear integral equations, by L. B. Rall; problems in qualitative behaviour of solutions of nonlinear Volterra equations, by J. A. Nohel; the numerical solution of nonlinear integral equations and related topics, by B. Noble; some nonlinear integral equations of hydrodynamics, by D. H. Hyers; nonlinear integral equations of radiative transfer, by T. W. Mulliken. Most of the treatments plunge straight into function space in a difficult attempt to establish existence and uniqueness theorems appertaining to nonlinear analysis. However, even where positive conclusions have been achieved, there still remains a considerable gap between the theory and its applications to the concrete equations of applied mathematics. A different note is struck in the long and well-balanced article by Dr. B. Noble, who provides a thorough account of his topic amply illustrated at each stage by examples taken from life. The two final papers deal in a recondite manner with areas of physics where nonlinear integral equations play an indispensable part. Whether this book succeeds in its professed aim of inaugurating the title subject as a viable autonomous discipline is open to question, but it certainly provides a very fair picture of present-day activities in a central field of analysis.

Mathieu functions were first introduced to the British mathematical public by Whittaker and Watson. Then came the highly readable 1947 monograph by McLachlan, who presented a wealth of new results and an effective symbolism. Now at last, by adequately exploiting the fundamental theorems of Floquet and Ince before actually constructing solutions, Prof. F. M. Arscott has provided a coherent modern account of Mathieu's equation, concentrating largely on essentials but always clearly indicating where further details can be pursued. This work occupies the first half of his book, and paves the way for

an examination of Hill's and Lamé's equation, and allied equations, in the second half. It is difficult to think of any alternative source in English which renders this somewhat recalcitrant material so readily accessible. The author in his preface suggests that Lamé's and allied functions might afford a superior means of solving the boundary- and initial-value problems of mathematical physics than computer supplied numerical solutions. Certainly no mathematician would attempt a numerical solution if moderately tractable analytical machinery were available, but Arscoott's own model example on pp. 228 *et seq.* shows how far this is from being the case for even the simplest problems relating to ellipsoidal domains. If a practical motivation for studying the higher functions must be cited, it ought to be that their Frobenius or asymptotic expansions reveal the approximate structure of potentials and waves at important special neighbourhoods beyond numerical scope.

The book by van der Pol (now deceased) and Brammer is the second impression of the 1959 edition of their well-known text. Its success stems not merely from their treatment of the operational calculus, but also from their refreshing approach to various important modern infinitesimal processes. For example, their remarks on Stieltjes integration make clear just why such an integral should be introduced and what kind of part it could usefully play. An appreciation of this factor is, for most students, the critical step on learning any new technique. Although primarily addressed to applied mathematicians, and mathematically minded physicists and engineers, it contains much of interest to mathematical analysts. Historical aspects are not overlooked, and it comes as no surprise to find that Dirac's delta function had been extensively used by Oliver Heaviside. A confusing notational mishap occurs on p. 7, where the same symbol, used in different senses, appears in both the Fourier series and Fourier integral.

M. A. JASWON

## MATHEMATICAL TABLES FROM THE U.S.S.R.

### Mathematical Tables Series

#### Volume 23. Tables of the Function

$$F(z) = \int_0^z e^{-x^2} dx$$

in the Complex Form. By K. A. Karpov. Translated by D. E. Brown. Pp. xxv+497. 140s. net.

#### Volume 27. Tables of the Function

$$w(z) = e^{-z^2} \int_0^z e^{-x^2} dx$$

in the Complex Domain. By K. A. Karpov. Translated by D. E. Brown. Pp. xxi+519. 140s. net.

Volume 37. Tables of Elliptic Integrals, Part 1. By V. M. Belyakov, P. I. Kravtsova and M. G. Rappoport. Pp. xiii+647. 140s. net.

Volume 38. Tables of the Legendre Functions, Part 2. By M. I. Zhurina and L. N. Karmazina. Translated by Praenjit Basu. Pp. xiii+409. 120s. net.

(London and New York: Pergamon Press, 1964 and 1965.)

THESE volumes of Russian tables, which are supplied with an English translation of the introductory matter, were printed in Poland. The pages are generally clean, without too many rules, and the old-style fount is pleasant and legible, though the slightly exaggerated "heads and tails" occasionally make for a crowded appearance when the setting is close. Differences are not printed.

Volumes 23 and 27 deal with the error integral for a complex argument in polar form,  $z = \rho \exp(i\theta)$ , in each case giving the real and imaginary parts of the function

at an opening to five decimals. In Volume 23 the range of  $\theta$  is  $45^\circ$  ( $0^\circ.3125$ )  $48^\circ.75$  ( $0^\circ.625$ )  $55^\circ$  ( $1^\circ.25$ )  $65^\circ$  ( $2^\circ.5$ )  $90^\circ$  and the range of  $\rho$  depends on  $\theta$  with a lower limit of 0, 0.5, 1, 1.5, 2, 3.5 or 4 and an upper limit of 3, 4 or 5, at intervals of 0.001 or 0.01. A subsidiary table gives  $F$  for real  $z$  ( $\theta = 0$ ),  $\rho = 0$  (0.001) 10. Volume 27 was compiled in connexion with a problem on the propagation of radio waves, and supplies information for the ranges:

$$\theta = 0^\circ, \rho = 0 \text{ (0.001) } 2 \text{ (0.01) } 10;$$

$$\theta = 0 \text{ (2.5}^\circ) 30^\circ \text{ (1.25}^\circ) 35^\circ \text{ (0.625}^\circ) 45^\circ,$$

where  $\rho$  has an upper limit 5, a lower limit, depending on  $\theta$ , between 0 and 3.5, and intervals 0.01, 0.001 or 0.0002. Schematic representation of the argument range and functional relations provides assistance in reading the tables and in extending the range.

The incomplete elliptic integral of the third kind:

$$\Pi(n, k^2, \varphi) = \int_0^\varphi (1+n \sin^2 x)^{-1} (1-k^2 \sin^2 x)^{-1/2} dx$$

depends on three parameters and is correspondingly tiresome to compute and to tabulate. If we are prepared to accept a fairly crude interval for  $\varphi$ , then Volume 37 gives good information with seven significant figures for the ranges  $n = -1$  (0.005)  $-0.98$  (0.01)  $-0.94$  (0.02)  $-0.88$  (0.03)  $-0.85$  (0.05) 0,  $k^2 = 0$  (0.01) 1.0,  $\varphi = 0^\circ$  ( $1^\circ$ )  $90^\circ$ .

When  $n = 0$ , this is a table of the incomplete integral of the first kind,  $F(k^2, \varphi)$ . Subsidiary tables give:

$$E(k^2, \varphi) = \int_0^\varphi (1 - k^2 \sin^2 x) dx$$

for  $k^2 = 0$  (0.01) 1,  $\varphi = 0^\circ$  ( $1^\circ$ )  $90^\circ$ , and also various elementary integrals which occur as coefficients in expansions of the elliptic integrals. The second part of the table (not yet published) is to give similar information about  $\Pi(n, k^2, \varphi)$  for positive  $n$  in the range from 0 to 100, and the same ranges of  $k^2$  and  $\varphi$ .

The Legendre function  $P_n(x)$  with  $n = -\frac{1}{2} + i\tau$  occurs in potential problems when the boundary is a bowl. In Part 1 (Volume 22) tabulation was effected for the range

$$0 \leq \tau \leq 50, -0.9 \leq x \leq 0.9.$$

The present Volume 38 is concerned with the range  $x > 1$ , and in detail gives seven decimal places for:

$$x = 1.1 \text{ (0.1) } 2.0 \text{ (0.2) } 5.0 \text{ (0.5) } 10.0 \text{ (10) } 60,$$

$$\tau = 0 \text{ (0.01) } 50.$$

These volumes are, of course, highly specialized, but they cope with functions the published tabulation of which has hitherto been inadequate or non-existent. The efficient librarian, if he cannot afford the volumes, will at least make the appropriate notes in the Fletcher, Miller, Rosenhead and Comrie *Index*. T. A. A. BROADBENT

## RUSSIAN UNIVERSITY COURSE IN THERMODYNAMICS

### Thermodynamics

By Prof. I. P. Bazarov. Translated by F. Immirzi. Translation edited by A. E. J. Hayes. Pp. xvi+287. (London and New York: Pergamon Press, 1964.) 50s. net.

**THERMODYNAMICS**, which is by the professor of statistical physics at the Moscow State University, is the first part (it is said in the preface) of a course on thermodynamics and statistical physics as given in the physical and physico-mathematical faculties of the Soviet universities. As such it is emphatically a physicists', rather than a chemists' or engineers' thermodynamics, and it is in the fine tradition of physical thermodynamics and statistics exemplified by an earlier Russian text translated into English, the well-known one by Landau and Lifshitz.

As also in that invaluable *Statistical Physics*, the illumination of thermodynamics by use of problems is

one of the most important features of the present volume. There are altogether a hundred and twenty, many of them extremely interesting and ingenious. For example, in the chapter on the Second Law the student has to explain Wien's light valve paradox, and also the Chinese 'ducking toy', both of which seem to imply perpetual motion of the second kind. Problems of this sort—and there are many such—are of great value in making the student think, and that is something of far greater importance than the attainment of a mere dexterity.

However, I believe that some of these problems, in the abbreviated forms in which they are presented, are far too difficult, and also that one or two of the author's solutions (as given in a fifty-four page appendix) are a little tendentious. For example, his solution to Problem 39 involves some special pleading in order to obtain what he regards as a purely thermodynamic answer to Gibbs's paradox.

One other defect in the book (as it seems to me) is the occasional intrusion of political theory. Thus in the introduction it is asserted that the law of conservation of energy "is indissolubly bound with the dialectic-materialist ideology". Again, dealing with the Second Law, certain bourgeois scientists—notably Clausius and Jeans—are severely taken to task for having developed the notion of the universe's heat death. This, it is said, "leads directly to religious superstition—the existence of God".

Yet these ideological bows having been made, the book provides a quite fascinating discussion of physical thermodynamics and it does so moreover with a happy recognition of the subjects' truly international character.

The treatment of the Second Law is very detailed and is based on Carathéodory's method, but also contains much that is original and perceptive. The author further discusses the concept of negative absolute temperatures (and the bearing of this concept on the conventional formulation of the law) arising from Purcell and Pounds's experiments on the reversal of nuclear spins in crystals of lithium fluoride. Other important sections are concerned with the thermodynamics of radiation and plasma, of dielectrics and magnetic substances, of surface phenomena and phase transitions. Nernst's heat theorem is presented and there is also an outline of Onsager's theory and its application to the thermo-electric effect.

The translator has had a difficult task and this has mostly been well achieved. Yet some of the arguments are not so clear as they should be and there are certain ambiguities. To what extent these are due to the original, or to the difficulties of conveying into another language the subtleties of thermodynamic discussion, it is hard to say. Thus, the book in translation is to be recommended not so much for definitive statement as for its power of conveying a real sense of interest in its subject-matter and for its originality. It is certainly a book which I wish to possess.

K. G. DENBIGH

## ULTRASOUND FOR THE CHEMIST AND BIOCHEMIST

### Ultrasound

*Physical, Chemical, and Biological Effects.* By Isaak Efimovich El'piner. Authorized translation from the Russian. Pp. viii + 371. (New York: Consultants Bureau, 1964.) 22.50 dollars.

IT is a major difficulty, for those embarking on any research work in which ultrasound is used as a tool rather than as the subject of study, that there is a dearth of suitable text-books. Until recently, the books available were almost all written from the point of view of the physicist or engineer, or occasionally from the point of view of the specialist in physical medicine.

Now books are beginning to appear which are aimed at the needs of other users of ultrasound, and *Ultrasound:*

*Physical, Chemical, and Biological Effects* supplies a very genuine need. It is translated from the Russian by F. L. Sinclair and is doubly welcome for the large amount of Russian work which it summarizes.

Dr. El'piner has clearly been an important member of a large group of research workers whose work, owing to the curse of Babel, is not normally known in Britain or the United States. However, a warning must be given that the title of the book as it appears in English is misleading.

In a book of more than 300 pages, only nine are devoted to the physics of the subject. This is, of course, a brief summary of the basic principles only. The next twenty pages are devoted to the physical aspects of cavitation and give a good description of shock-wave production. There is then a valuable chapter on the neglected subject of ultrasonic luminescence.

After this uneven coverage of the physical effects, the book launches into nearly 200 pages of description of what is clearly Dr. El'piner's main field of work, the action of ultrasound on organic chemical substances whether synthetic or natural. A very large proportion of the work described is Russian and much of this is Dr. El'piner's work.

It is quite impossible to summarize the contents of these chapters, just as it is impossible to summarize a dictionary. The book is really a work of reference that will prove invaluable to anyone intending to embark on comparable work, but it inevitably is very heavy going as reading matter. The complexity of the subject is due to the large number of factors that influence the action of ultrasound in a single chemical compound. Naturally enough, the normal physical parameters of ultrasound, intensity, frequency and duration, have to be supplemented by temperature and pH that determine most chemical activity. What is less obvious is that the nature of the dissolved gas and the pressure in the irradiation chamber are of even greater importance, while some substances have a catalytic action even in trace amounts.

The possible permutations of all these parameters with the whole range of synthetic and natural organic substances produce an almost limitless experimental field. For good measure, in some cases different workers have obtained different results in what were ostensibly similar circumstances. Unfortunately, no pattern appears from the mass of recorded observations. Sometimes a dissolved gas will accelerate a chemical change, sometimes the same gas will inhibit the change. Sometimes ultrasound produces polymerization, but much more often it depolymerizes. Rarely is the chemical change produced freely enough to tempt the chemical engineer to consider its commercial exploitation—though sometimes small amounts of compounds are obtained by ultrasound that defy other methods of 'obtention' (if one of the translator's favourite words may be borrowed).

The major criticism of this work is the inadequacy of the information regarding the irradiation methods used. In the biological fields the problem of intensity measurement has proved very severe in non-cavitating conditions. Radiation pressure measurements have now become almost universal in the medical field, but they cannot be used in cavitating fields with comparable success. For example, on p. 63 reference is made to irradiation at "frequency 600 kc, intensity 5 W/cm<sup>2</sup> of emitting surface, duration of irradiation 4 h". Lower on the same page it is implied that cavitation occurs in such circumstances. Most reference books quote Keesche as indicating that the threshold of cavitation at this frequency varies from about 50 W/cm<sup>2</sup> if water is not degassed, to about 100 W/cm<sup>2</sup> in degassed water.

Clearly the cavitation phenomenon, which seems to produce temperatures of 10,000° C momentarily as a cavity collapses, is of crucial importance in determining the chemical activity or inactivity of ultrasound. It would have been a much more valuable book had information been given not merely as to whether audible

cavitation was occurring but also what routine was used to check the intensity. It is common knowledge that standing waves in tanks make the level of ultrasonic intensity vary greatly with quite minor differences of depth of liquid. Where irradiation is maintained for hours at high intensity evaporation might well cause the actual intensity to vary over a wide range.

The final sixty pages summarize the published work in ultrasonic surgery and diagnosis. Here the Russian work appears to be much less in relation to the rest of Europe and the United States. Here again it is tantalizing to be shown ultrasonic tomograms produced by El'piner with no indication of the method of scanning by which they were obtained.

The whole effect of the book has been to intensify greatly my long-standing desire to visit the U.S.S.R. and study the work at close quarters. Many other readers will feel a similar need to obtain a fuller account of what is clearly very important work. DOUGLAS GORDON

## GEMMOLOGY

### Gem Testing

Seventh edition. By B. W. Anderson. Pp. 383. (London: Temple Press Books, Ltd., 1964.) 60s. net.

IT is seventy years since Sir Henry Miers, when an assistant in the Department of Mineralogy at the British Museum (Natural History), gave a short series of lectures in London on gemmology, as the scientific study of gemstones is now called, and it is nearly sixty years since the National Association of Goldsmiths set up an Education Committee to arrange lectures on the subject and to organize examinations. This Committee was reconstituted in 1931 as the Gemmological Association of Great Britain.

Since then gemmology has made steady progress in Britain and in many other countries. Great impetus was given to it by the introduction of synthetic rubies made by the Verneuil process in 1904, and it received another fillip by the arrival on the market of cultured pearls in 1921. Since then, many new synthetic stones have been manufactured, and also there are now grown in Japan the new 'Biwa' cultured pearls which have no nucleus of mother-of-pearl but instead only little stripes of pearl-secreting mantle. Fortunately, radiographs serve to distinguish these from natural pearls.

As each new synthetic stone or imitation appears, means must be found of detecting and identifying it. Successive editions of *Gem Testing* have kept pace with this demand. The new edition also announces new discoveries of natural stones—a new source of ruby in Tanganyika, and of emeralds in Rhodesia and Pakistan—as well as new developments in technique and apparatus.

Among synthetics the 'Chatham' emeralds receive more attention than formerly, and new arrivals are the 'Lechleitner emeralds', made in Innsbruck, in which a thin shell of emerald is made to grow on a seed crystal or cabochon of beryl of inferior colour. Here, as in many other cases, the study of the microscopic inclusions in the stones is a great help in identification. B. W. Anderson has also discovered a marked difference in transparency to ultra-violet rays between the 'Chatham' emeralds and natural stones which are opaque to all rays shorter than 3000 Å.

Fluorescence, excited by either long- or short-wave ultra-violet light, has been used for many years as an aid in gem testing. Several fresh examples of its usefulness are given in this edition, especially in the sections on diamond where the variable fluorescence of different kinds or colours of diamond is described. There are developments also in the use of fluorescence excited by X-rays, and this is coming into use for testing cultured pearls and seems to be replacing the endoscope which was much used

for the detection of cultured drilled pearls. Unfortunately Anderson reports that the endoscope is no longer being made.

In the earlier chapters, which deal in detail with apparatus and methods, new sections describe dispersion, the magnetic properties of gemstones, and methods of handling and housing gemstones. The last-mentioned subject is dealt with here for the first time in a new chapter that will prove very welcome to collectors.

Certainly, as Anderson warns in his introduction, the book provides no light reading, but the more one reads it the more one finds that is new and useful.

W. CAMPBELL SMITH

## METAZOAN EVOLUTION

Dynamics of Metazoan Evolution: The Origin of the Coelom and Segments

By R. B. Clark. Pp. x+313. (Oxford: Clarendon Press; London: Oxford University Press, 1964.) 48s. net.

*DYNAMICS of Metazoan Evolution* is concerned with the part which has been played in evolution by the mechanical needs of animals and with the importance of taking such functional considerations into account in the construction of phylogenies. Dr. R. B. Clark considers that the comparative morphology of structures which have been elaborated in solving mechanical problems during evolution has received inadequate attention and intends his book to remedy this. After considering theories which attempt to explain the evolution of the coelom and the segmentation of invertebrates, the variety of methods of movement and their underlying mechanism in acoelomates and coelomates are discussed.

An account of gastropod locomotion occurs in the chapter headed "The Acoelomate Condition" and the changes of *Metridium* and nematode locomotion are discussed in the chapter on "The Coelomate Condition". Such an argument is striking when taken out of context, but such treatment was found to be necessary in support of the author's argument that the solution of the same mechanical problem is frequently arrived at in the same way in widely different animals. This point has been made before, but in the present book it is backed by examples from a variety of phyla and is argued at length. In the next chapter Dr. Clark considers the septate condition and the refinements in the movement and locomotion of animals with hydraulically arranged muscular antagonism which this permits. Undulatory swimming is then considered and a brief account given of this form of locomotion in invertebrates and vertebrates. That segmentation evolved independently in the invertebrates and vertebrates and is not necessary for sinusoidal swimming is shown by the occurrence of such movements in non-segmented invertebrates. But in the chordates the action of the lateral musculature is increased in efficiency by division into segmental blocks. If this section is less satisfactory than its predecessors it probably arises from two causes. First, the author is well known for his researches on polychaetes which are, mechanically, a central group in the investigation of the 'hydraulic organism'. Secondly, in spite of the investigation that has been devoted to the locomotion of fishes, there is no entirely satisfactory analysis of the action of the longitudinally arranged muscles and their relation to the complex and variable pattern of myocommata found in these animals. If the chordates do not play a part in the main theme of the book comparable with that of the annelids, they serve to emphasize the point that the concept of metameric segmentation is imprecise and of little explanatory value.

In the final chapter the present theories of the phylogeny of the metazoa are exposed to criticism based on

the idea that any hypothetical form should be a viable animal conforming to the laws of mechanics. These do not change with the passage of time, however much physical and biotic factors of the environment may have altered during evolutionary history. The case is closely argued and, although the author does not hazard his own suggestion for a family tree, he wisely emphasizes that not only organisms but also phylogenies evolve with increasing knowledge and that all that is known and is relevant must be taken into account when constructing phylogenies rather than selected aspects of the biology of a group. The importance which he attaches to mechanics leads him to question the accepted view that polychaetes are nearer than oligochaetes to the ancestral protoannelid stock. Although this view may not gain immediate acceptance, it will certainly demand a fresh examination of all the evidence bearing on the problem.

An aspect of such major evolutionary steps as the acquisition of a coelom or metameric segmentation which is rarely considered is the selective advantages of an incompletely evolved state. It is easy to see how, once evolved, the coelomate, or pseudocoelomate, marks an advance on the acoelomate. Parenchyma which is slightly more fluid or which has a few cracks in it presumably enabled an ancestral form to move a little faster, to gather a little more food and to leave a few more progeny than one with a more viscous interior. Dr. Clark is well aware of this problem and touches on it here and there, but one would like to see this aspect of evolution carefully examined. In what field could this be better essayed than in that of mechanics? But one can scarcely complain of this as an omission from the present book, which leaves little to be desired in clarity and rigour as an example of functional morphology applied to phylogeny.

G. CHAPMAN

## CANCER RESEARCH

### Advances In Cancer Research

Vol. 8. Edited by Prof. Alexander Haddow and Sidney Weinhouse. Pp. viii+482. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 12s. 6d.

THERE are nine contributors to Volume 8 of *Advances in Cancer Research*. E. L. Wynder and D. Hoffman dedicate their masterpiece of reviews on experimental tobacco carcinogenesis (covering the past decade) to the American Cancer Society. Backed by more than 700 references and occupying about half the volume, we are instructed in the production of cigarettes through stages of tobacco curing, addition of humectants, seasoning and casing material. The tobacco products, fractions, and single components are then thoroughly analysed in a detailed search for carcinogens. A selective summary of experiments on the biological testing of these carcinogens on a variety of animals and birds extends in a concise tabular form occupying 37 pages.

There is no doubt as to the carcinogenic action of tobacco products, particularly smoke condensates, but with rare exceptions, however, passive inhalation of tobacco smoke has not produced true bronchogenic cancer in laboratory animals. This is not surprising as there is no epidemiological evidence that indirect inhalation of tobacco smoke contributes to the development of lung cancer (pathways other than the respiratory tract may convey carcinogens to the lungs).

In interpreting experimental findings the authors suggest that tobacco smoke condensates contain tumour initiators in the form of a variety of polynuclear and heterocyclic aromatic hydrocarbons which would be complete carcinogens if present in large concentrations. However, on chemical findings, smoke condensate contains

more tumour promoters than initiators and the promoting activity of these condensates is regarded as being greater than their initiating activity. Prophylaxis is aimed at reduction of harmful products rather than prevention through abstinence. A table full of hopeful suggestions includes measures aimed at reduction of total smoke condensate, and the reduction of all-important but somewhat neglected cilia-toxic agents.

In another fascinating chapter entitled "Carcinogenesis Related to Foods Contaminated by Processing and Fungal Metabolites", H. F. Kraybill and M. B. Shimkin deal mainly with two topics, trout hepatoma and mycotoxins. A marked increase in hepatomas unaccompanied by cirrhosis has coincided with advances in processing methods which have replaced wet by dry pelleted diets in trout hatcheries. The neutral lipid fractions from tumorigenic rations play the major aetiological part, but the authors cautiously include other possible factors including genetic predisposition, viral, bacterial and parasitic infections, ionizing radiation, defoliants, pesticides and fungal metabolites (some of the last-mentioned two are lipid-solvent soluble).

Mycotoxins are discussed in general and aflatoxins in particular. They are possibly the most potent hepatocarcinogens in a variety of animals and in some are associated with cirrhosis. Aflatoxins are derived from a fungus which may affect groundnuts during growth, gathering, or drying. There are no data available showing that this natural hazard affects man, nor is a screening test for aflatoxin or a metabolite of aflatoxin in the urine yet available. Lactones derived from the metabolites of other fungi and fungal metabolites from rice contaminated with *Penicillium islandicum* are carcinogenic in animals. How many of the quarter of a million or so fungal species in Nature will induce cancer?

In a review of nucleolar chromosomes (mainly in normal cells) M. J. Kopeć and G. M. Matheyko point out that there is no universally accepted interpretation of the structure or function of the nucleolus in the interphase nucleus and there are no clear differences, morphological or biochemical, between normal and malignant nucleoli. Nucleolar chromosomes, their nucleolar organizers, and the origin of nucleolar substance are considered in detail. Variations in puffing patterns in different cells and tissues, both natural and experimentally induced, are also described. The final third of the chapter summarizes present knowledge and contains speculations on the relationship of chromosomes, nucleoli, nuclei and other subcellular structures on the control of cellular differentiation which in turn hinges on the cancer problem.

The nuclear proteins of neoplastic cells are considered by H. Busch and W. J. Steele. The authors emphasize that the understanding of the chemistry of nuclear protein is in its infancy and the techniques for isolating nuclei from cells of tumours or normal tissues are not yet perfect. They describe the difficulties in procedures for isolating nucleoli, chromosomes, nuclear ribosomes and other nuclear components. About half the review concerns the proteins associated with DNA and in particular with the basic histone proteins of the deoxyribonucleoprotein complex the systematics of which are still somewhat confused. Techniques for the fractionation of histones are more advanced than methods for acidic nuclear proteins, but apart from *RP2-L*, a histone fraction in tumours of murine and human origin, there appears to be no evidence that there are differences between the histones of tumours and of other tissues.

In a beautifully illustrated chapter, A. F. Howatson gives a clear and concise account of the structure of tumour viruses of laboratory animals and birds and of those more immediately concerned with man (human papilloma, SV40, adeno-virus type 12). Advances in negative-staining techniques and contrast reversal photography permit direct comparison of electron micrographs with suitably orientated models. Most virus particles of a

particular species conform to a definite structural pattern, but aberrant forms are not unusual and there is still hope (in the case of mouse leukaemia virus) that 'tails' are not entirely artefactual. A scheme of classification based on symmetry, nucleic acid type, presence of envelope, and site of assembly of virus in the cell does not result in any clear-cut separation of oncogenic viruses from non-oncogenic viruses.

This volume maintains the high standard of this series. The summary of contents before each chapter is particularly helpful for rapidly obtaining information. The only adverse criticism is that there are a few spelling mistakes. I hope the word 'homograph' is not a new addition to transplantation terminology! F. C. CHESTERMAN

## SOIL SCIENCE

### Elements of Tropical Soil Science

By Dr. T. Eden. Second edition. Pp. ix+164. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1964.) 13s. 6d. net.

### Practical Soil Science

(Israel Program for Scientific Translations.) By N. N. Nikol'skii. Translated by Rivka Nadel. Pp. v+240. (Distributed by: Oldbourne Press, London; 1963.) 72s.

### The Physical Chemistry and Mineralogy of Soils

By C. E. Marshall. Vol. 1: Soil Materials. Pp. ix+388. (New York, London and Sydney: John Wiley and Sons, Inc., 1964.) 90s.

DR. EDEN'S *Elements of Tropical Soil Science* is directed particularly to farmers and planters in the tropics rather than to the generality of students, but nevertheless for the greater part comprises chapters on the widely applicable principles of morphology, the physical and chemical properties of soils, and on manuring and the availability of nutrients. The chapters on erosion and the maintenance of soil fertility have a more specific direction to tropical circumstances, but for the rest tropical references are confined to illustrative examples. Because the author has lived his life in the East and in Africa these illustrations are usually very good indeed, as in his treatment of the soil catena and of laterization.

The book is descriptive, so that errors of technology (for example, the definition of the water table is wrong) have no catastrophic consequences.

Dr. Nikol'skii's *Practical Soil Science* is approved in the U.S.S.R. as a text for the faculties of agrochemistry, soil science and agronomy. Nearly three-fifths of the book is a laboratory manual for the quantitative chemical analysis of soil, and another fifth describes physical analyses. Only the remainder concerns itself with the field description and mapping of soil profiles, a subject which Russians have pioneered.

The chemical section is divided into chapters on the analysis of whole soil, including the determinations of organic matter, carbonates and mineral elements; on the determination of exchangeable cations and of the base exchange capacity; on soil acidity; and on the analysis of water soluble material. Every determination is described in detail and the formulae for working out the results are written down. Some disorder is noticeable, matter being placed in the sections somewhat arbitrarily and occasionally in the wrong company. It is in the character of the book that in only one case is the agronomic significance of a determination discussed, and the reader is left to wonder just what is the agronomic relevance of a fusion analysis of whole soil. This part is a welcome addition to laboratory texts for students.

The physical analyses include measurements of soil density and volume weight, moisture content by straight-

forward gravimetric methods, shrinkage, stability of aggregation, and mechanical analysis in some detail. The author follows the American usage in identifying, by definition, texture and mechanical composition, which is at best an impoverishment of the language and at worst a source of confusion. Selected soil states for the measurement of moisture content are rather arbitrary, and soil permeability is covered without mention of Darcy's law. All this is conventional descriptive soil physics which has little relation to the application of the laws of physics to soil.

The translation of the sections on soil morphology and mapping has evidently been difficult and some interpretation is still left to the reader. The elements of profile description are familiar enough, but here the wealth of illustrative examples drawn from a wide experience of soils representative of the great world groups is quite fascinating. The description of soil structure is very well illustrated, although not everyone would limit the definition of structure to the shapes and sizes of aggregates. If this part is more appropriate to a general textbook of pedology than to a practical manual, the balance is restored by the chapter on field survey procedure and mapping.

For more than thirty years Dr. Marshall has been one of the leading contributors to our understanding of the physical chemistry of colloidal materials in the soil. *The Physical Chemistry and Mineralogy of Soils* distils the essence of his experience of that field and its appearance is a notable event.

The various chapters summarize the basic physico-chemical concepts and methods applicable to soil constituents; discuss in some detail the crystal structures of minerals which characterize the clay fraction and the coarser fractions; but necessarily are reduced to more empirical descriptions of organic matter. They go on to describe the molecular adsorption of gases and liquids, principally water; the electrochemistry of clays and the closely allied subjects of the exchange and fixation of ions from extraneous solutions; and conclude with a discussion of the electrokinetic and physical properties of cataphoresis, coagulation, viscosity and swelling.

Let it be said at once that this is not a course text-book. Much of the groundwork is taken for granted or the reader is directed to the standard works. Rather little is worked out in detail and fully developed. This is essentially a coverage of a wide range of diverse kinds of experimental work described in just sufficient detail to enable the author to place each item in the general picture which emerges. The wealth of references makes this a source book and a launching pad for further researches.

It is Dr. Marshall's particular difficulty that he has to try to reconcile two concepts which are in some ways mutually incompatible. On the one hand the Stern and Gouy layers, which are at the foundations of modern analysis, are regions of non-uniform distributions of electric potential and ionic concentration. On the other hand, the conventional terminology of ionic activities, degree of dissociation, membrane potential, Donnan equilibrium and so on imply uniformity of these quantities. Success in his task is not aided by some hasty composition, as when he tells us that "the arithmetical average of the electrostatic potentials becomes the logarithmic average of the ionic activities".

The outlines are again blurred late in the book when the author contrasts what he alleges to be a surface tension model of clay swelling with the Gouy layer picture. The latter does, of course, account physically for a swelling pressure, while the former proves to throw no light whatever on the mechanism of swelling.

These are small criticisms to put against the great service that the author has rendered in putting a little order into this heterogeneous field and in particular for reproducing for a wider public some truly magnificent electron photomicrographs.

E. C. CHILDS

**Handbook of Chemistry and Physics**

A Ready-Reference Book of Chemical and Physical Data. Edited by Robert C. Weast, Samuel M. Selby and Charles D. Hodgman. Forty-fifth edition. Pp. xxi+1470. (Cleveland, Ohio: The Chemical Rubber Co.; Oxford: Blackwell Scientific Publications, Ltd., 1964.) 147s.

OVER the past fifty years the *Handbook of Chemistry and Physics* has built for itself a prominent place on the bookshelves of all chemists and physicists, and in many cases a prominent niche on the desk or laboratory bench.

The latest edition, the forty-fifth, which appears under the joint editorship of Dr. R. C. Weast (editor-in-chief), Dr. S. M. Selby and Prof. C. D. Hodgman, embodies a number of major changes, not the least of which is the change of format. The increase in material presented can be realized from the fact that not only has the page size been doubled, but also the volume has maintained the same thickness as the forty-fourth edition.

Concomitant with the increase in page size are the greatly enlarged tables of physical constants of organic compounds and of inorganic compounds, and it is claimed that data for approximately 5,000 more compounds have been added to this edition. The table dealing with isotopes has been completely revised and brought up to date, and the section on the elements, by C. R. Hammond, has been greatly extended. While the format of certain tables has been completely changed, some of them are now presented in the form of two pages of the old size side by side on the new page. It is to be hoped that in later editions all tables will be presented in the new style, as it is a great aid to clarity.

The old system of presenting the material in ten major sections has been completely revised, and it now appears in six: (A) Mathematical Tables; (B) Elements and Inorganic Compounds; (C) Organic Compounds; (D) General Chemical; (E) General Physical Constants; (F) Miscellaneous. All in all, this, along with the binominal code system, leads to considerable ease in references from the index or contents.

The *Handbook of Chemistry and Physics* in its latest edition should be within easy reach of all scientists, whether they work in Government, industrial, academic or private institutions, and whatever their discipline or nationality. Dr. Weast and his colleagues, along with the publishers, the Chemical Rubber Co., are to be congratulated on this production. 147s. is a small price to pay for so much information so readily available.

**Encyclopedia of Chemical Technology**

By Kirk-Othmer. Vol. 5: Chlorine to Colors for Foods, Drugs and Cosmetics. Second completely revised edition. Pp. xiv+884. (New York and London: Interscience Publishers, a division of John Wiley and Sons, Inc., 1964.) 338s.

THE publication of each volume of the second edition of 'Kirk-Othmer' is eagerly awaited by every user of the *Encyclopedia of Chemical Technology*. Once again the editors are to be congratulated on their presentation of a further series of reviews, of the expected high standard, covering subjects ranging from "Chlorine" to "Colors FD&C".

It is worthy of note that the articles on "Chlorocarbons and Chlorohydrocarbons", "Chocolate and Cocoa", and "Coal" are reviewed by experts working in the United Kingdom. It is to be appreciated that these articles are intended for use mainly by American technologists. The articles on "Chlorocarbons and Chlorohydrocarbons" are particularly informative and contain many references to synthetic processes, chemical reactions, uses and toxicity. The quoted threshold limit values (TLV), also referred to as maximum allowable (or permissible) concentrations (MAC or MPC) for chlorinated hydrocarbons, are up to date, and, although the fact is not mentioned, are generally accepted as international standards. The broad

spectrum cyclodiene insecticides of the aldrin, dieldrin, endrin series are adequately reviewed from a technological point of view, but in light of their high toxicity some emphasis should be placed on their restrictive uses in practice (that is, to tolerance limits of residues in foods).

For food technologists there are informative articles covering "Chocolate and Cocoa", "Coffee" and "Colors FD&C". References to other food additives are found under articles on "Chlorophyll", "Cinnamaldehyde" and "Citric Acid". As one compares the lists of permissible and non-permissible food colours accepted by the United States with those accepted by other countries, one realizes that international standardization on this topic is long overdue.

In the medical field, interesting articles deal with "Choline" and with "Coagulants and Anticoagulants".

Other subjects reviewed include "Clays", important to so many industries; "Coal", where we are reassured that during the next generation there will be many developments in coal production and utilization; and "Coated Fabrics", an article dealing with the use of plastics in industry.

For the technologist seeking information on analytical techniques, there are adequate reviews on "Chromatography" and "Colorimetry and Fluorimetry". Under "Chromatography", more emphasis could be given to the technique of thin-layer chromatography. This article closes with a glossary of terms and symbols encountered in chromatography.

Finally, I must mention the comprehensive review on "Color Photography", an article that includes many references to the chemical processes and materials involved in this subject. The article closes with special references of colour photography in colour television and in infra-red aero applications.

K. FIELD

**Current Aeronautical Fatigue Problems**

Proceedings of a Symposium held in Rome, 23-25 April, 1963. Edited by J. Schijve, J. R. Heath-Smith and E. R. Walbourne. Pp. viii+499. (New York and London: Pergamon Press, 1964.) 120s.

THIS symposium was the third of a series concerned exclusively with fatigue problems, organized jointly by the International Committee on Aeronautical Fatigue and the Advisory Group for Aeronautical Research and Development—organizations respectively and more familiarly known as I.C.A.F. and A.G.A.R.D. A total of seventeen papers is presented, representing the United Kingdom, the United States, France, Germany, Italy and the Netherlands.

The papers are arranged in three sections, dealing with (i) elevated temperature effects (6 papers); (ii) crack propagation and residual static strength (7 papers); and (iii) structural fatigue testing (4 papers). Each section is helpfully introduced by a short technical preface; while, according to the custom for such records of proceedings, the discussions which followed the individual papers are fully reported. The contributions are very variable in regard to bibliographic references; but in the volume as a whole more than 170 references are listed—in the main to very recent work.

To review a symposium of papers is in many ways an unsatisfactory task; but on this occasion the work is eased by the careful standardization of the form of the reports. This is an authoritative volume that will be indispensable to all concerned with the elimination of fatigue failures, for much of the work reported is applicable to other fields than the aeronautical industry alone. It is no reflexion on the other two sections to single out for special mention the section on crack propagation: this records a remarkably detailed and increasingly accurate understanding of the basic mechanics of the phenomenon and a number of elegant experimental procedures are reported.

B. N. COLE

# A NEW CLASS OF FAULTS AND THEIR BEARING ON CONTINENTAL DRIFT

By PROF. J. TUZO WILSON, O.B.E.

Institute of Earth Sciences, University of Toronto

**TRANSFORMS and half-shears.** Many geologists<sup>1</sup> have maintained that movements of the Earth's crust are concentrated in mobile belts, which may take the form of mountains, mid-ocean ridges or major faults with large horizontal movements. These features and the seismic activity along them often appear to end abruptly, which is puzzling. The problem has been difficult to investigate because most terminations lie in ocean basins.

This article suggests that these features are not isolated, that few come to dead ends, but that they are connected into a continuous network of mobile belts about the Earth which divide the surface into several large rigid plates (Fig. 1). Any feature at its apparent termination may be transformed into another feature of one of the other two types. For example, a fault may be transformed into a mid-ocean ridge as illustrated in Fig. 2a. At the point of transformation the horizontal shear motion along the fault ends abruptly by being changed into an expanding tensional motion across the ridge or rift with a change in seismicity.

A junction where one feature changes into another is here called a transform. This type and two others illustrated in Figs. 2b and c may also be termed half-shears (a name suggested in conversation by Prof. J. D. Bernal). Twice as many types of half-shears involve mountains as ridges, because mountains are asymmetrical whereas ridges have bilateral symmetry. This way of abruptly ending large horizontal shear motions is offered as an explanation of what has long been recognized as a puzzling feature of large faults like the San Andreas.

Another type of transform whereby a mountain is transformed into a mid-ocean ridge was suggested by S. W. Carey<sup>2</sup> when he proposed that the Pyrenees Mountains were compressed because of the rifting open of the Bay of Biscay (presumably by the formation of a mid-ocean ridge along its axis). The types illustrated are all dextral, but equivalent sinistral types exist.

In this article the term 'ridge' will be used to mean mid-ocean ridge and also rise (where that term has been used meaning mid-ocean ridge, as by Menard<sup>3</sup> in the Pacific basin). The terms mountains and mountain system may include island arcs. An arc is described as being convex or concave depending on which face is first reached when proceeding in the direction indicated by an arrow depicting relative motion (Figs. 2 and 3). The word fault may mean a system of several closely related faults.

**Transform faults.** Faults in which the displacement suddenly stops or changes form and direction are not true transcurrent faults. It is proposed that a separate class of horizontal shear faults exists which terminate abruptly at both ends, but which nevertheless may show great displacements. Each may be thought of as a pair of half-shears joined end to end. Any combination of pairs of the three dextral half-shears may be joined giving rise to the six types illustrated in Fig. 3. Another six sinistral forms can also exist. The name transform fault is proposed for the class, and members may be described in terms of the features which they connect (for example, dextral transform fault, ridge-convex arc type).

The distinctions between types might appear trivial until the variation in the habits of growth of the different types is considered as is shown in Fig. 4. These distinctions are that ridges expand to produce new crust, thus leaving residual inactive traces in the topography of their former positions. On the other hand oceanic crust moves down under island arcs absorbing old crust so that they leave no traces of past positions. The convex sides of arcs thus advance. For these reasons transform faults of types a, b and d in Fig. 4 grow in total width, type f diminishes and the behaviour of types c and e is indeterminate. It is significant that the direction of motion on transform faults of the type shown in Fig. 3a is the reverse of that required to offset the ridge. This is a fundamental difference between transform and transcurrent faulting.

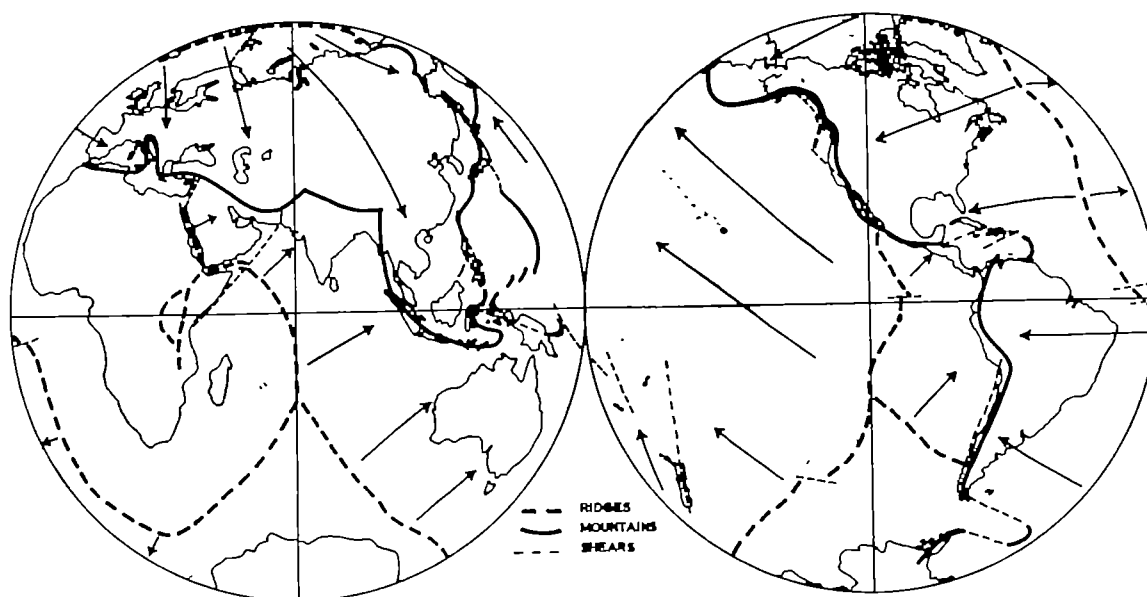

Fig. 1. Sketch map illustrating the present network of mobile belts, comprising the active primary mountains and island arcs in compression (solid lines), active transform faults in horizontal shear (light dashed lines) and active mid-ocean ridges in tension (heavy dashed lines).

Many examples of these faults have been reported and their properties are known and will be shown to fit those required by the constructions above. If the class as a whole has not heretofore been recognized and defined, it is because all discussions of faulting, such as those of E. M. Anderson, have tacitly assumed that the faulted medium is continuous and conserved. If continents drift this assumption is not true. Large areas of crust must be swallowed up in front of an advancing continent and re-created in its wake. Transform faults cannot exist unless there is crustal displacement, and their existence would provide a powerful argument in favour of continental drift and a guide to the nature of the displacements involved. These proposals owe much to the ideas of S. W. Carey, but differ in that I suggest that the plates between mobile belts are not readily deformed except at their edges.

The data on which the ensuing accounts are based have largely been taken from papers in two recent symposia<sup>4,5</sup> and in several recent books<sup>6,7</sup> in which many additional references may be found.

**North Atlantic ridge termination.** If Europe and North America have moved apart, an explanation is required of how so large a rift as the Atlantic Ocean can come to a relatively abrupt and complete end in the cul-de-sac of the Arctic Sea. Fig. 5 illustrates one possible explanation.

Fig. 2. Diagram illustrating the four possible right-hand transforms. a, Ridge to dextral half-shear; b, dextral half-shear to concave arc; c, dextral half-shear to convex arc; d, ridge to right-hand arc.

Fig. 3. Diagram illustrating the six possible types of dextral transform faults. a, Ridge to ridge type; b, ridge to concave arc; c, ridge to convex arc; d, concave arc to concave arc; e, concave arc to convex arc; f, convex arc to convex arc. Note that the direction of motion in a is the reverse of that required to offset the ridge.

Fig. 4. Diagram illustrating the appearance of the six types of dextral transform faults shown in Fig. 3 after a period of growth. Traces of former positions now inactive, but still expressed in the topography, are shown by dashed lines.

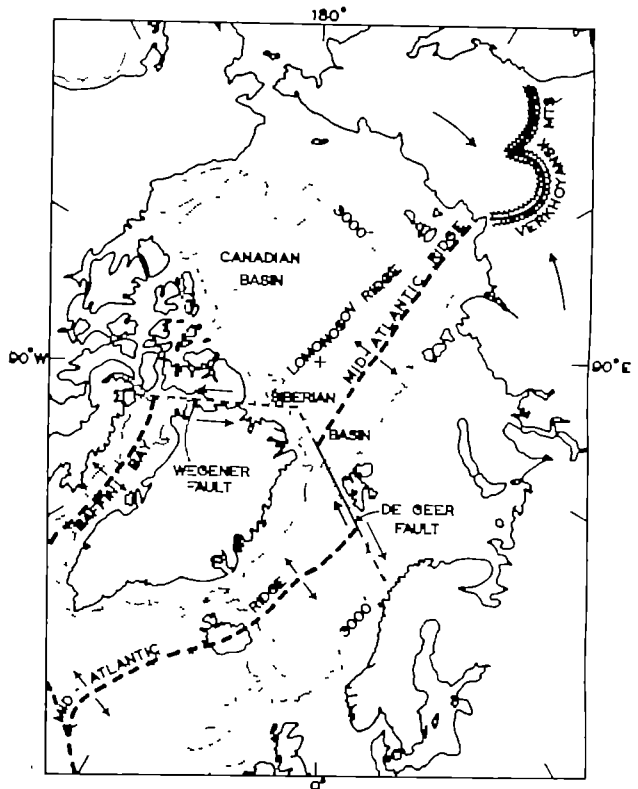

Fig. 5. Sketch map of the termination of the Mid-Atlantic ridge by two large transform faults (Wegener and De Geer faults) and by transformation into the Verkhoyansk Mountains.

Wegener<sup>8</sup> suggested that the strait between Greenland and Ellesmere Island was formed by a fault, here postulated to be a sinistral transform fault (ridge-ridge type). Wegmann<sup>9</sup> named another between Norway, Spitsbergen and Greenland, the De Geer line, which is here regarded as a dextral transform fault (ridge-ridge type). The extension of the Mid-Atlantic ridge across the Siberian basin was traced by Heezen and Ewing<sup>10</sup>, while Wilson<sup>11</sup> proposed its transform into the Verkhoyansk Mountains by rotation about a fulcrum in the New Siberian Islands. In accordance with the expectations from Fig. 4a earthquakes have been reported along the full line of the De Geer fault in Fig. 5, but not along the dashed older traces between Norway and Bear Island and to the north of Greenland. The Baffin Bay ridge and Wegener fault are at present quiescent. W. B. Harland<sup>12</sup> and Canadian geologists have commented on the similarities of Spitsbergen and Ellesmere Island.

**Equatorial Atlantic fracture zones.** If a continent in which there exist faults or lines of weakness splits into two parts (Fig. 6), the new tension fractures may trail and be affected by the existing faults.

The dextral transform faults (ridge-ridge type) such as AA' which would result from such a period of rifting can be seen to have peculiar features. The parts AB and B'A' are older than the rifting. DD' is young and is the only part now active. The offset of the ridge which it represents is not an ordinary faulted displacement such as a transcurrent fault would produce. It is independent of the distance through which the continents have moved. It is confusing, but true, that the direction of motion along DD' is in the reverse direction to that required to produce the apparent offset. The offset is merely a reflexion of the shape of the initial break between the continental blocks. The sections BD and D'B' of the fault are not now active, but are intermediate in age and are represented by fracture zones showing the path of former faulting.

## Already a familiar sight in hundreds of laboratories

The Perkin-Elmer model F.11 Gas Chromatograph, introduced as recently as March 1964, is already established as the ideal instrument for everyday analysis. Successful applications with compounds as diverse as waxes, phenols, fatty acids and amines prove its versatility.

Designed and built at Beaconsfield, the F.11 offers the user all the latest operating features, such as temperature programming, dual column base-line compensation and capillary column resolution.

Make sure to write or ring for details of the Perkin-Elmer Model F.11—the Gas Chromatograph which combines top performance, reliability and low cost.

## The NEW **SHANDON** LARGE VERTICAL ELECTROPHORESIS APPARATUS

### EASIER TO MANIPULATE

Cover lifts off giving easy access to buffer and electrode compartments.

### SAFER TO OPERATE

Shrouded terminals are built into the electrode compartments.

### ALL PLASTICS CONSTRUCTION

No danger of broken glass, no sharp corners, light in weight.

AND BETTER LOOKING, TOO!

The apparatus consists of three sections.

1. Base, 17 in. x 7½ in. with integrally moulded buffer and electrode compartments.
2. Triangular paper holding frame standing on the base.
3. Transparent cover enclosing electrode and buffer compartments and minimizing evaporation.

The new Shandon LARGE VERTICAL ELECTROPHORESIS apparatus can accommodate up to six filter paper strips 50 mm. wide, draped over the paper holding frame. Specimens are applied at the apex.

Recommended power supply is the Shandon VoKam Constant Voltage/Constant Current Power Supply.

Write or phone to-day for full details.

Fig. 6. Diagram illustrating three stages in the rifting of a continent into two parts (for example, South America and Africa). There will be seismic activity along the heavy lines only

Fig. 7 shows that the Mid-Atlantic ridge and the fracture zones in the equatorial Atlantic may well be a more complex example of this kind. If so the apparent offsets on the ridge are not faulted offsets, but inherited from the shape of the break that first formed between the coasts of Africa and the Americas. Fig. 7 is traced from Heezen, Bunce, Hersey and Tharp<sup>12</sup> with additions to the north from Krause<sup>13</sup>. The fracture zones are here held to be right-hand transform faults and not left-hand transcurrent faults as previously stated. If the fracture zones can be traced across the Atlantic and are of the type postulated, then the points where they intersect the opposite coasts are conjugate points which would have been together before rifting.

It seems possible that the old fault in Pennsylvania and the offset of the Atlantic Coast described by Drake and Woodward<sup>14</sup> are of the same nature, although it is suggested that it is not usual for a fracture zone to follow a line of seamounts, and that the fracture zone may extend eastward, not south-east.

A possible explanation of the termination of the Carlsberg ridge. Another type of transform fault is found in the Indian Ocean and Arabian Gulf opened during the Mesozoic and Cenozoic eras by the northward movement of India, new ocean floor must have been generated by spreading of the Carlsberg ridge. This ends abruptly in a transcurrent fault postulated by Gregory<sup>15</sup> off the east coast of Africa. A parallel fault has been found by Matthews<sup>16</sup> as an offset across the Carlsberg ridge and traced by him to the coast immediately west of Karachi. Here it joins the Ornaoh-Nal and other faults<sup>17</sup> which extend into Afghanistan and, according to such descriptions as I can find, probably merge with the western end of the Hindu Kush. This whole fault is thus an example of a sinistral transform fault (ridge-convex arc type).

At a later date, probably about Oligocene time according to papers quoted by Drake and Girdler<sup>18</sup>, the ridge was extended up the Red Sea and again terminated in a sinistral transform fault (ridge-convex arc type) that forms the Jordan Valley<sup>19</sup> and terminates by joining a large thrust fault in south-eastern Turkey (Z. Ternek, private communication). The East African rift valleys are a still later extension formed in Upper Miocene time according to B. H. Baker (private communication).

The many offsets in the Gulf of Aden described by Laughton<sup>20</sup> provide another example of transform faults adjusting a rift to the shape of the adjacent coasts.

Possible relationships between active faults off the west coast of North America. This tendency of mid-ocean ridges to be offset parallel to adjacent coasts is thought to be evident again in the termination of the East Pacific ridge illustrated in Fig. 9. The San Andreas fault is here postulated to be a dextral transform fault (ridge-ridge type) and not a transcurrent fault. It connects the termination of the East Pacific ridge proper with another short length of ridge for which Menard<sup>21</sup> has found evidence off Vancouver Island. His explanation of the connexion—that the mid-ocean ridge connects across western United States—does not seem to be compatible with the view that the African rift valleys are also incipient mid-ocean ridges. The other end of the ridge off Vancouver Island appears to end in a second great submarine fault off British Columbia described by Benioff<sup>22</sup> as having dextral horizontal motion.

In Alaska are several large faults described by St. Amand<sup>23</sup>. Of the relations between them and those off

Fig. 7. Sketch (after Krause and Heezen *et al.*) showing how the Mid-Atlantic ridge is offset to the left by active transform faults which have dextral motions if the rift is expanding (see Fig. 4a). —, Mid-ocean ridge; —, active fault; ---, inactive fault trace; . . . , hypothetical extension of fault

Fig. 8. Sketch illustrating the end of the Carlsberg mid-ocean ridge by a large transform fault (ridge-convex arc type) extending to the Hindu Kush, the end of the rift up the Red Sea by a similar transform fault extending into Turkey and the still younger East African rifts

Fig. 9. Sketch map of the west coast of North America showing the approximate location of a submarine thrust fault along the Aleutian trench, the Denali faults (after St. Amand), the San Andreas and another large transform fault (after Benioff) and part of the East Pacific ridge and another mid-ocean ridge (after Menard)

the coast he writes: "If the two systems represent one consistent system, some interesting possibilities arise. One that the San Andreas and Alaska Complex is a gigantic tear fault, along which the Pacific Basin is being slid, relatively speaking under the Alaska Mainland, and the Bering Sea. On the other hand, if the whole system is a strike-slip fault having consistent right-lateral offset, then the whole of the western north Pacific Basin must be undergoing rotation".

St. Amand was uncertain, but preferred the latter alternative, whereas this interpretation would favour the former one. Thus the Denali system is considered to be predominantly a thrust, while the fault off British Columbia is a dextral transform fault.

At a first glance at Fig. 9 it might be held that the transform fault off British Columbia was of ridge-concave arc type and that it connects with the Denali system of thrust faults, but if the Pacific floor is sliding under Alaska, the submarine fault along the Aleutian arc that extends to Anchorage is more significant. In that case the Denali faults are part of a secondary arc system and the main fault is of ridge-convex arc type.

*Further examples from the Eastern Pacific.* If the examples given from the North and Equatorial Atlantic Ocean, Arabian Sea, Gulf of Aden and North-west Pacific are any guide, offsets of mid-ocean ridges along fracture zones are not faulted displacements, but are an inheritance from the shape of the original fracture. The fracture zones that cross the East Pacific ridge<sup>11</sup> are similar in that their seismicity is confined to the offset parts between ridges. An extension of this suggests that the offsets in the magnetic displacements observed in the aseismic fracture zones off California may not be fault displacements as has usually been supposed, but that they reflect the shape of a contemporary rift in the Pacific Ocean. More complex variants of the kind postulated here seem to offer a better chance of explaining the different offsets noted by Vacquier<sup>12</sup> along different lengths of the Murray fracture zone than does transcurrent faulting. If the California fracture zones are of this character and are related to the Darwin rise as postulated by Hess, then the Darwin rise should be offset in a similar pattern.

The southern Andes appear to provide an example of compression combined with shearing. The compressional features are obvious. The existence of dextral shearing is also well known<sup>13</sup>. It is suggested that the latter may be due to the transformation of the West Chile ridge into a dextral transform fault (ridge-convex arc type) along the Andes which terminates at the northern end by thrusting under the Peruvian Andes (Fig. 10).

The observation that there is little seismicity and hence little movement south of the point where the West Chile ridge intersects the Andes can be explained if it is realized that the ridge system forms an almost complete ring about

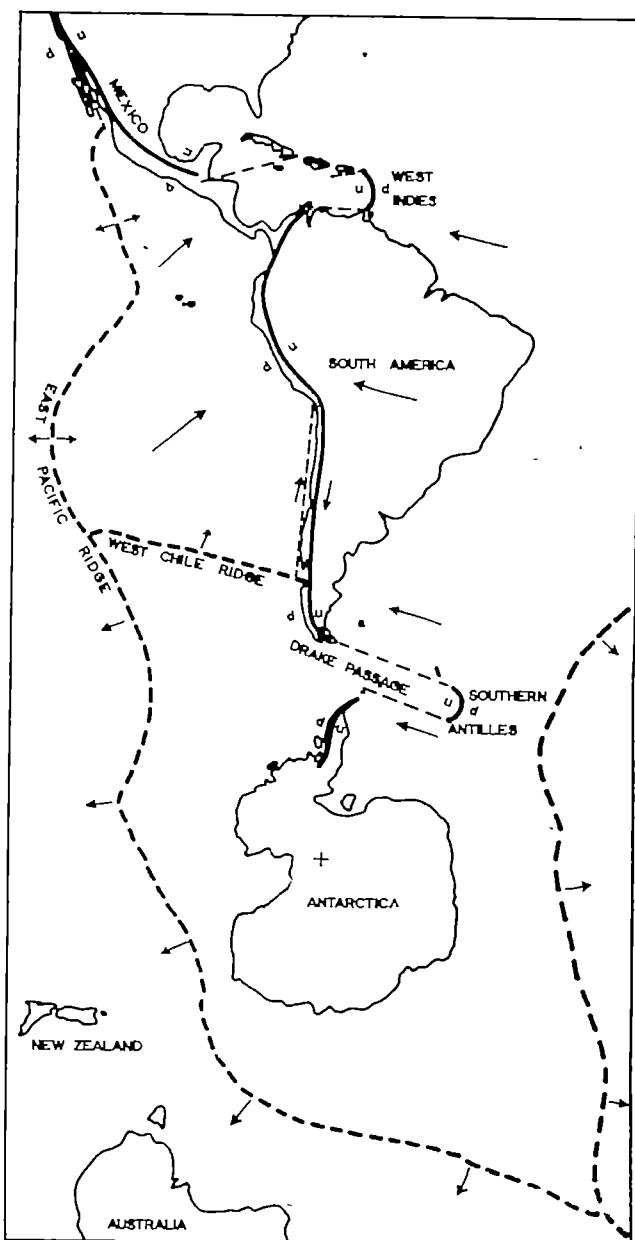

Fig. 10. Sketch map of Mexico, South America, Antarctica and part of the mid-ocean ridge system (heavy dashed lines) illustrating that the great loop of the ridge about Antarctica can only grow by increasing in diameter. Transform faults are shown by light dashed lines

Antarctica, from which expansion must everywhere be directed northwards. This may explain the absence of an isthmus across Drake Passage.

It would also appear that the faults at the two ends of the South Antilles and West Indies arcs are examples of dextral and sinistral pairs of transform faults (concave-concave arc types). According to Fig. 4 both these arcs should be advancing into the Atlantic and inactive east-west faults should not be found beyond the arcs.

This article began by suggesting that some aspects of faulting well known to be anomalous according to traditional concepts of transcurrent faults could be explained by defining a new class of transform faults of which twelve varieties were shown to be possible.

The demonstration by a few examples that at least six of the twelve types do appear to exist with the properties predicted justifies investigating the validity of this concept further.

It is particularly important to do this because transform faults can only exist if there is crustal displacement and proof of their existence would go far towards establishing the reality of continental drift and showing the nature of the displacements involved.

I thank the Departments of Geodesy and Geophysics and of Geology and Churchill College, University of Cambridge, for the opportunity to write this article, those whose data I have used, and colleagues—especially Sir Edward Bullard, W. B. Harland, H. H. Hees, D. H. Matthews and F. J. Vine—for advice; and Sue Chappell and Sue Vine for assistance. This is a contribution to

the Vela Uniform programme and to the Canadian Upper Mantle Project.

## ACTIVATION ANALYSIS

SINCE the first international meeting on activation analysis, held in Vienna six years ago, the technique has been vigorously developed for practical use in many areas of science and technology. Comprehensive reviews of recent progress and current research were provided at two large gatherings which were held in April 1965. More than sixty papers were read at the Second International Conference on Modern Trends in Activation Analysis, sponsored by the Texas Agricultural and Mechanical University, the United States Atomic Energy Commission, Euratom and the International Atomic Energy Agency. This meeting, which was held at College Station, Texas, during April 19–22, attracted 500 participants. The Advanced Seminar on Activation Analysis, organized by the General Atomic Division of the General Dynamics Corporation, met in San Diego during April 26–28 and was attended by 230 research workers. The programme comprised 45 invited papers, with emphasis on practical applications. In the report which follows, an asterisk is used to identify papers given at the San Diego meeting.

Activation analysis is basically a simple process, involving the examination and assay of the radioactivity induced in a sample after bombardment by neutrons or other missiles. Its potentialities are limited by the imagination of the experimenter, who may not find it easy to devise or interpret an experiment making full use of the extraordinary sensitivity of a method which, for some elements, reaches 1,000 or even a million times beyond the limit of achievement by other means.

Sensitivity is not all-important, even in the estimation of trace impurities. A. A. Smales (Atomic Energy Research Establishment, Harwell) emphasized the superiority of emission spectroscopy and spark source mass spectrometry where (as is often the case) a general survey of all possible impurities is desired. If the offending trace element can be nominated, activation analysis and mass

spectrometric isotope dilution analysis are preferable. At the ultimate limit of sensitivity, activation analysis has the important advantage of freedom from reagent contamination errors; even so, fluorescent X-ray spectrometry will be chosen when it is necessary to discover the location of a small quantity of impurity within a specimen.

Neutrons are commonly used for the activation of the sample to be analysed, partly because they are readily available at low cost, but also because of their indifference to the potential barriers which limit the access of charged particles to the target nuclei. The possibilities offered by thermal neutrons and by 14-MeV neutrons (from a deuterium-tritium discharge tube) have been fairly thoroughly explored, but interesting work remains to be done at intermediate energy levels, as E. L. Steele (General Atomic, San Diego) explained.

By careful choice of neutron energy, the selectivity of fast neutron activation analysis may be greatly increased. It is, for example, difficult to distinguish oxygen from fluorine when 14-MeV neutrons are used, since both elements yield the same product, by the reactions  $^{19}\text{F}(n,\alpha)^{16}\text{N}$  and  $^{18}\text{O}(n,p)^{18}\text{N}$ . The first of these processes has a threshold (for neutron energy) at 1.5 MeV and the second at 10 MeV. For energies between these limits, only fluorine will form  $^{16}\text{N}$ . Threshold differences may be exploited for the estimation of magnesium in the presence of aluminium, since the reaction  $^{24}\text{Mg}(n,p)^{24}\text{Na}$  has a threshold at 4.7 MeV, while the interfering process  $^{27}\text{Al}(n,\alpha)^{24}\text{Na}$  has a threshold at 3.1 MeV. Selection of neutron energy also permits the estimation of silicon in the presence of phosphorus, chromium in the presence of manganese and sulphur in the presence of chlorine.

Steel uses a 3-MeV Cockcroft-Walton generator to accelerate positive ions ( $p, d, ^3\text{He}$  or  $\alpha$ ) which are used to bombard a target; Li, Be, B, C, Al, V and others are being investigated. By appropriate choice of particle,

accelerating potential and target material, approximately monoenergetic neutrons are produced in useful quantities and with energies in the range from a few keV to 20 MeV, allowing many reaction thresholds and resonance absorptions to be utilized.

For the estimation of elements with  $Z < 10$ , thermal neutrons are of little value. Fast neutrons are more serviceable, but interferences from neighbouring elements are often troublesome. Activation analysis with  $^3\text{He}$  ions is attractive; because of the large binding energy, many useful reactions occur at relatively low incident energies, from 12 MeV downward. E. Ricci (Oak Ridge National Laboratory) reported a sensitivity of  $3 \times 10^{-11}$  g in the determination of oxygen by the reaction  $^{16}\text{O}(^3\text{He}, p)^{14}\text{F}$ , using a 25- $\mu\text{amp}$  beam of  $^3\text{He}^{++}$  ions. E. L. Steele\* discussed the difficulty associated with the poor penetration of heavy ions, and suggested that vaporization of the sample under bombardment (in a suitable container) might be tolerated. He quoted excellent sensitivities for the detection of several light elements, but pointed out that the products are mostly positron emitters all producing annihilation radiation of energy 0.51 MeV. Consequently, identification of the desired activity must be done by resolution of complex decay curves rather than by pulse-height analysis.

O. Engelmann (Centre d'Etudes Nucleaires de Saclay) used photons, protons and  $\alpha$ -particles at energies up to 40 MeV for the determination of light elements (C, N, O, F) in reactor materials, by non-destructive methods with sensitivities better than  $10^{-7}$  g.

Although thermal neutrons are not effective in the activation analysis of light elements, secondary processes occurring in a nuclear reactor may sometimes be pressed into service. H. J. Born (Institut für Radiochemie der Technischen Hochschule, Munich) explained how the successive reactions  $^6\text{Li}(n, \alpha)^3\text{H}$  and  $^{16}\text{O}(t, n)^{14}\text{F}$  may be used for the determination of oxygen or lithium in a system containing both elements. Knowledge of the oxygen content of lithiumbutyl (a polymerization catalyst) is significant in the manufacture of plastics and the exact measurement of the lithium content of many substances is important both for geochemical problems and for checking the purity of reactor materials.

Most of the samples submitted to activation analysis display a complex pattern of induced radioactivity after neutron bombardment. In rare instances the desired activity can be separated by simple instrumental means, as, for example, in the estimation of oxygen in steel, where the  $(n, p)$  reaction on  $^{16}\text{O}$  gives  $^{16}\text{N}$ . The  $\gamma$ -radiation emitted by this isotope is of such high energy (6.13 and 7.13 MeV) that it can be detected without interference from any of the other activities induced in the steel specimen.

More often a detailed separation must be attempted, either by chemical means (after irradiation, when contamination from reagents is no longer a hazard) or by fairly elaborate  $\gamma$ -ray spectrum analysis. Chemical separation is necessary to achieve the ultimate sensitivity, but instrumental techniques are sometimes convenient. M. D. Cohan (Armed Forces Radiobiology Research Institute, National Naval Medical Center, Bethesda) described a counting system incorporating an electronic computer to provide immediate calculation of analytical results, with appropriate graphical or digital presentation to the user, during the course of the experiment. Several laboratories record complex  $\gamma$ -ray spectra on magnetic tape for subsequent resolution with the help of electronic computers.

Present applications of activation analysis fall into four main categories. In science the main interest is in geochemistry and in cosmochemistry, inferred from analysis of meteorites. Knowledge of trace element concentrations both in the Earth's crust and in extra-terrestrial material has been radically altered during the past ten years by the use of activation analysis. The determination of

major constituents in meteorites by fast neutron activation analysis is of growing importance for the study of the rarer meteorites, where the limited supply of material makes non-destructive analysis particularly attractive. J. R. Vogt (University of Kentucky) described methods for the rapid estimation of oxygen and silicon in meteorites. An IBM '1410' computer is used to handle the experiment data and to calculate the results, allowing complete analyses to be performed at the rate of 60/h.

The most widely useful industrial application of activation analysis is the estimation of oxygen in steel. With automatic equipment now available, a complete analysis can be made in 2 min or less, with accuracy better than 2 per cent. D. E. Wood (Kaman Nuclear, Colorado Springs) reported a careful comparison with the commonly used vacuum fusion method, concluding that activation analysis with 14 MeV in the reaction  $^{16}\text{O}(n, p)^{16}\text{N}$  is more reliable, since it accounts for the whole of the oxygen in the sample, regardless of chemical form; in vacuum fusion the oxygen may not be fully extracted.

Technical advances made possible by the development of relatively cheap and simple neutron generators were typified in the nuclear analysis system for coal, described by T. O. Martin (Texas Nuclear Corporation, Austin). This equipment measures the carbon, oxygen, silicon and aluminium content of coal on a conveyor belt, using a neutron generator and monitor, two scintillation spectrometers and a four-channel system for data analysis. The carbon and oxygen contents are measured by the inelastic scattering of fast neutrons, using a  $\gamma$ -ray spectrometer positioned near the generator. Aluminium and silicon are estimated by activation analysis, with the help of a second spectrometer placed about 40 sec downstream. The calorific value of the coal can be estimated with reasonable accuracy from the carbon content. The percentage of moisture is related to the oxygen content, especially in wet coals, and the proportions of aluminium and silicon are a guide to the ash content.

The compactness of fast-neutron activation analysis equipment has already been exploited in building apparatus which, when delivery can be effected, will help to determine the composition of the lunar surface. Additional information can be gained from the direct or indirect examination of various capture and scattering reactions, not necessarily associated with the induction of radioactivity.

An ingenious example of this approach was discussed by R. L. Caldwell\* (Socony Mobil Oil Co., Dallas, Texas) in relation to the analysis of oil-bearing rocks. A small generator, with suitable detection equipment, is lowered into a borehole, where a 20–200- $\mu\text{sec}$  pulse of 14-MeV neutrons is delivered. The aftermath of this pulse is revealed by measuring the thermal neutron flux (using a boron trifluoride counter) or the promptly-emitted  $\gamma$ -rays from various nuclei after neutron activation.

The production of thermal neutrons depends on slowing-down by collision, mainly in oil or water. The rate at which the burst of thermal neutrons dies away is influenced by the presence of elements such as sodium and chlorine, with large capture cross-sections. The die-away measurement technique can be made to yield a remarkable amount of information on the presence of oil, fresh water or salt water and has the advantage of being able to work effectively through the iron pipe that normally lines the borehole.

In clinical science the principal application of activation analysis is in the determination of trace elements. The experimenter's task is often made difficult by the presence of interfering elements. Sodium is the most significant, because of its abundance in biological material and of its large neutron capture cross-section. Ion exchange techniques are effective in the removal of sodium, but may also remove, in whole or in part, the trace elements which

it is desired to measure. M. P. Menon and R. E. Wainardi (Texas Agricultural and Mechanical University) described a simple procedure based on the precipitation of carrier and active sodium by a mixture of *n*-butanol and hydrochloric acid, removing the  $^{24}\text{Na}$  (and, incidentally, most of the chlorine activity) but having little effect on the remaining trace elements in the irradiated specimen.

The metabolism of manganese offers many problems illustrating the potentialities—and pitfalls—of activation analysis. Manganese-levels in biological fluids (blood serum, cerebro-spinal fluid, bile, saliva) are seldom above 1  $\mu\text{g}/100\text{ ml}$ . Attempts to remove sodium by dialysis before neutron irradiation have been criticized with some justification, because of contamination with manganese from the buffer solution.

To estimate the error involved in this procedure, E. Kanabrocki\* (Veterans Administration Hospital, Hines, Illinois) exposed buffer solution to neutron bombardment before dialysis of unirradiated samples of various biological fluids. Corrections of up to 25 per cent were found to be necessary. In the estimation of manganese in urine, the contribution made by the buffer solution to the final result was found to be as high as 72 per cent; some workers would put this figure at 100 per cent, since it has been asserted that the mammalian kidney does not excrete manganese at all.

Determination of tissue concentrations is the first step towards elucidating the physiological or biochemical role of an element. Discussing the homeostasis of manganese, G. Cotzias\* (Brookhaven National Laboratory, Upton, New York) reported animal experiments showing that dietary manganese-levels can be increased by a factor of 180–200 before the tissue-levels will be doubled. The mechanism for this very effective control is not known, but there is evidence—as yet inconclusive—that the adrenal hormone influences excretion of manganese.

Another unsolved problem was illuminated by E. D. Bird (University of Florida) in an investigation of trace elements in urine. Hypertrophic cartilage from rachitic rats can be mineralized *in vitro* by incubation in urine from patients actively forming kidney stones, but not in urine from normal patients. Minute amounts of zinc, manganese or cadmium are found to inhibit mineralization *in vitro*. Bird reported, however, that patients with kidney stones generally excrete abnormally large amounts of zinc. In most cases, calcium-levels in urine were also elevated. It was noted that zinc excretion increased when the dietary intake of calcium was increased. Since most of the zinc in the body is incorporated in bone, it is not surprising that the metabolism of zinc is closely involved with that of calcium, but further work is needed to obtain a convincing picture of the relationship.

The intact human subject has been used in activation analysis, by exposing the body to a broad beam of fast neutrons and studying the induced activity with a whole-body counter. J. M. A. Lenihan\* (Western Regional Hospital Board, Glasgow) suggested that the total quantity of iodine in the thyroid gland (a matter of great interest to the physician) might be determined by irradiating the organ with thermal neutrons and assaying the induced activity due to  $^{131}\text{I}$ , by external scintillation counting. Sodium and chlorine, the main interfering activities, are rapidly cleared, but iodine is trapped in the thyroid—though some loss might occur as a result of the Sklar-Chalmers process. A total dose of  $10^{10}\text{ n/cm}^2$ , corresponding to 10 rads, should be adequate.

Forensic science offers scope to the activation analyst, since the investigation of material traces is frequently decisive in linking the suspect with the crime—or, what is just as satisfying, in dissociating him from it. Small samples of paint may be examined for evidence of common origin by estimation of trace elements (such as manganese, indium or copper) which are present at such low levels as to be of no obvious importance to the user and are there-

fore not controlled in the manufacturing process. For this reason, the concentrations usually vary considerably from one manufacturer (or even one batch) to another. V. P. Quinn (General Atomic, San Diego) suggested that gunpowder might be deliberately labelled with minute amounts of elements such as dysprosium and europium, readily determined by activation analysis. Collaboration among manufacturers would make it possible to determine not only whether a suspect has recently fired a gun (from the presence of powder traces on the hand or cheek) but also to identify the brand and calibre of the ammunition used.

M. J. Pro\* (U.S. Internal Revenue Service) reported that activation analysis had helped to fortify the revenue in more than 100 cases investigated during the past eighteen months. Approval is awaited from the Food and Drugs Administration for a scheme to label all narcotics produced in the United States; 16 elements will be available as markers and three will be used for each drug, allowing 560 combinations. Trace element analysis has been used successfully to identify whisky from an illicit still. Age claims (up to 100 years) in a consignment of imported brandy were refuted without the need for activation analysis by estimating the tritium content of the liquor.

Several groups are now examining the possibility of personal identification by trace element analysis of hair. W. S. Lyon\* (Oak Ridge National Laboratory, Tennessee) considered that positive identification was not yet possible, mainly because of differences in chemical composition among samples from the same head—or even from the same hair. R. F. Coleman\* (Atomic Weapons Research Establishment, Aldermaston) gave a preliminary report of investigations now being made to assess these difficulties and to develop a statistically reliable criterion for the identity of origin of two samples. J. P. W. Houtman\* (Reactor Institute, Delft) discussed the influence of diet on the composition of hair. In samples from 16 Trappist monks, for whom diet and environment were strictly controlled, concentrations of bromine, gold and zinc in the hair showed little variation from one individual to another, but considerable differences were found in the levels of arsenic, chromium and mercury.

Houtman also described work on activation analysis of pigments as an aid to the detection of false attribution of painting. White lead is a suitable material for investigations of this sort, since it has been used by painters for more than five centuries. Its major constituents are not appreciably activated by thermal neutrons, but a number of impurities, including silver, copper, antimony, zinc and bromine, are readily made radioactive. Estimation of these and other trace elements gives useful information as to the period in which the pigment was manufactured.

These two meetings gave evidence of the rapid spread of ideas and practical collaboration from the relatively small number of laboratories now engaged in activation analysis. The technique has not penetrated effectively into veterinary science or agricultural chemistry and is clearly capable of greater usefulness in biochemistry, both in the examination of trace element metabolism and in the determination of oxygen and nitrogen. Industrial applications, depending on the rapid analysis of raw materials or manufactured products, are also likely to grow with the increasing availability of modestly-priced neutron generators and pulse-height analysers.

The methods of activation analysis will not be fully exploited in scientific research and in industry until the subject finds a place in the undergraduate curriculum. The experimental principles are well within the grasp of the able student and can be taught in a relatively short time with simple equipment. There is also an evident need for a greater amount of systematic instruction at the postgraduate level, to meet the needs of research workers and teachers.

J. M. A. LENIHAN

## THE LONDON MATHEMATICAL SOCIETY

By PROF. H. DAVENPORT, F.R.S.

University of Cambridge

THIS year the London Mathematical Society completes one hundred years of existence, and the occasion was marked by a Centenary Meeting during July 13-15. There were seven lectures by eminent mathematicians, pure and applied, including two of the honorary members of the Society: Prof. Cartan of Paris and Prof. Nevanlinna of Helsinki. The lectures were delivered at University College, London, and a reception was also held in the rooms of the Royal Society on the evening of July 13 and a dinner at Goldsmiths' Hall on July 15.

It was particularly appropriate that the Centenary Meeting should have been held at University College, London, for it was there that the Society came into being. The proposal to form a mathematical society was first put forward by a small group of students there, and in the circular letter which invited attendance at a preliminary meeting on November 7, 1864, it was called the University College Mathematical Society. One of the students was George de Morgan, a son of Augustus de Morgan, professor of mathematics at the College during 1828-1831 and 1836-1866. Prof. de Morgan took a keen interest in the proposed Society, and it was due largely to his influence that it became a national learned society and not a College society. He was a mathematician with a broad range of interests, though not in the first rank as a discoverer, and was widely known for his writings (especially his *Budget of Paradoxes*), for his long connexion with the Royal Astronomical Society, and for his public service. (He was a prominent member of the Government Committee which reported on decimal coinage in 1863 in much the same terms as a similar Committee in 1963.) De Morgan's role in the foundation of the Society is commemorated by the De Morgan Medal, awarded every third year for distinguished contributions to mathematical knowledge.

The inaugural meeting of the London Mathematical Society, with twenty-seven members, was held on January 16, 1865, with Prof. de Morgan, the first president, in the chair. His address can still be read with interest. After stating the aims of the Society and giving his views with regard to the best policy by which to pursue them, he went on to urge the importance of a deeper study of the relationship between mathematics and logic. He also attacked (with good reason) the Cambridge examination system of the time.

The first vice-president was Dr. Thomas Hirst, who had studied at Marburg, Göttingen and Berlin, and was therefore, for a British mathematician of that period, unusually familiar with current mathematical developments on the continent. He was then professor of mathematical physics at University College, but succeeded de Morgan as professor of mathematics after the latter had resigned in 1866, in protest against an appointment made by the College Council under the influence (as he believed) of sectarian considerations.

The speed with which the Society attracted the support of leading mathematicians was remarkable. It must be attributed partly to the influence of de Morgan and Hirst and partly to the fact that the new society met a real need. The next two presidents after de Morgan were Sylvester and Cayley, the two greatest British pure mathematicians of the century, and a few years later H. J. S. Smith of Oxford served as president, and was followed by Lord Rayleigh. Rayleigh (then the Hon. J. W. Strutt) had joined the Society as a young man in its early days, and served for a long time on its Council. Another young mathematician of great originality, who

joined the Society while still a Cambridge undergraduate, was W. K. Clifford. Among other active members in the 1870's were Clerk Maxwell and William Thomson (later Lord Kelvin). There was a good deal of overlap between the memberships of the London Mathematical Society and of the Royal Astronomical Society, and some (for instance, Cayley) were active in both\*.

The aim of the Society has been constant from the day of its foundation: "the promotion and extension of mathematical knowledge". This aim has been mainly pursued by the publication of original papers; the Society has now published 104 volumes of the *Proceedings* and 89 volumes of the *Journal*. In addition there have always been monthly meetings, held nowadays in the rooms of the Royal Astronomical Society at Burlington House (except for one meeting each year, held in a university city other than London). The meetings served a somewhat different purpose in the early days of the Society than they do at present. They attracted men who were pursuing mathematical research, often of real originality, in isolation, while earning a living in some profession; and brought them into contact with the leading mathematicians of the country and with one another. A good deal of informal discussion occurred at the meetings, not always related to the papers that had been read. In recent times the meeting is usually given over to a lecture, often by a visiting mathematician from abroad, though occasionally there is a group of short talks on related topics instead.

The Society's publications have naturally reflected, in the character of their contents, the changing interests of the mathematicians of the country, and these have generally corresponded (though sometimes after a delay) with the interests of the mathematical world as a whole. Until the 1890's, there was a preponderance of papers on algebra and geometry. Then began the reign of analysis, which may be said to have continued, with variations of emphasis, until after the Second World War. In the 1930's and 1940's there were also many papers on number theory, and in particular on the geometry of numbers. In recent years, topology has loomed large, and algebra, in its various abstract forms, perhaps even larger. This is to speak only of pure mathematics; in applied mathematics the Society's publications, although containing many important papers, cannot now be considered to be fully representative of the tendencies of current research. This is mainly a consequence of the gradual evolution of various branches of applied mathematics into independent sciences with their own journals.

The scale of publication has had to be increased steadily over the years, and even now, with about 1,600 pages a year in the *Proceedings* and *Journal*, it barely keeps pace with the flow of good papers. The editing, printing and publishing of so much difficult mathematical material each year make heavy demands on the time and energy of the secretaries and editors, particularly as each paper involves correspondence with one or more referees, and consideration of referees' reports by the Council or the Journal Committee. The Society has never had any full-time paid staff.

Indeed, the Society has always been run with financial resources which were small in relation to its potential commitments, and has depended heavily on the devoted services of its officers. Dr. Glaisher (president 1884-86) recalled in his reminiscences on the occasion of the

\* More about the history of the Society will be found in Sir Edward Collingwood's article in *New Scientist*, 23, 94 (1965).

sixtieth anniversary of the Society (*Journal*, 1) that there was serious financial stringency in the early 1870's, and that a reduction in the scale of publication was then averted by a generous benefaction of £1,000 from Lord Rayleigh. "I do not think," wrote Glaisher, "that any gift was ever more opportune, or that any money was ever better spent."

One of the most eminent, and most devoted, members of the Society was G. H. Hardy, who was twice president (1926-28 and 1939-41) and twice secretary. He took on the secretaryship again immediately after his second term as president, at a time when war conditions made it difficult to carry on the Society's work. In his presidential address of 1928 he said: "The Society has always meant much more to me than any other Society to which I have belonged". He took a deep interest in the Society's affairs for more than forty years. It was mainly at his suggestion that the *Journal* should contain shorter (and possibly more readable) papers than the *Proceedings*. An editorial committee appointed by the Society is at present producing Hardy's *Collected Mathematical Papers*, and it is hoped that the first of the seven volumes will be published by the Clarendon Press this year. The Society has just published an extra volume of *Proceedings* in honour of the eightieth birthday of J. E. Littlewood, whose long and extremely fruitful collaboration with Hardy is without precedent in the history of mathematics.

The Society received its greatest benefaction to date under the will of Hardy's sister, Miss G. E. Hardy, who

survived him and died in 1963. This, like Rayleigh's benefaction, has been of great value, in that it has encouraged the Society again to expand its publications and to embark with greater confidence on further activities in pursuance of its aims. One of these is the organizing of instructional conferences of two- or three-week duration, at which courses of lectures on some important branch of mathematics in which current research is active are given by leading experts from Britain and from overseas. So far there has been one such conference on functional analysis and one on probability theory, and the third, on algebraic number theory, is to be held at the University of Sussex in September. Other recent developments are the foundation (jointly with other Societies) of the *Journal of Applied Probability*, and the publication (with support from the Science Research Council) of *Russian Mathematical Surveys*.

The London Mathematical Society of to-day, with its eight hundred members, is on a larger scale than could have been anticipated by its founders, but it is still animated by their spirit. The desire to help one another in the advancement of mathematical knowledge is still strong. This applies not only to the officers but also to the many members who share in the work (which is often onerous) of refereeing papers. There can be few British mathematicians who have not, at some time, profited greatly from the comments and criticisms of referees of the London Mathematical Society. In this way, as in others, the Society plays a part of vital importance in higher education and research.

## OBITUARIES

### Dr. J. W. S. Marr

JAMES WILLIAM SLESSER MARR, who died on April 29 in his sixty-third year, made outstanding contributions to polar exploration and marine biology. While reading classics at Aberdeen he was chosen as a Scout to take part in the Shackleton-Rowett Expedition of 1921-22 in the *Quest*. After the death of Sir Ernest Shackleton in South Georgia, the expedition failed to achieve its main objective, but much was accomplished over a wide scientific field, notably on the islands of South Georgia, Elephant, Gough and Tristan da Cunha. He returned to Aberdeen to complete his studies and was awarded the M.A. degree in classics in 1924, and the B.Sc. degree in zoology in 1925.

Marr then took part in the British Arctic Expedition with T. A. Worsley and G. Algarsson, and described the plants of West Spitzbergen, Northeast Land and Franz Joseph Land, and the results of dredging in 78°-82° N. After a year as Carnegie Scholar at the Marine Laboratory in Aberdeen, he joined the *Discovery Investigations*. During 1928-29 he worked in the R.R.S. *William Scoresby*, mainly on oceanographic surveys of the South Georgia whaling grounds but also on a winter trawling survey of the Patagonian shelf within a few days steaming of the Falkland Islands. His next voyage (1929-30) was in the R.R.S. *Discovery* with the British, Australian and New Zealand Antarctic Expedition, doing extensive work in Kerguelen, Heard Island and off Enderby Land. In 1931-33 he was in the R.R.S. *Discovery II* working on a programme which included oceanographic observations round the winter ice-edge, and a survey of the South Orkney Islands. An oceanographic survey of the Ross Sea was one of the outstanding events of his next voyage, in 1935-37; but the main feature of the work, much of it in the drift from the Weddell Sea, was his concentration on the study of krill (*Euphausia superba*) on which the baleen whales feed. He experimented with new methods of sampling, fishing deeper and deeper nets to catch the

eggs and early larval stages, and doing his best to measure the extent to which adult krill avoid the ship and towed nets in daylight, and to find a practical method for quantitative sampling which would overcome the patchiness of the krill, which occurs in shoals or swarms.

He deals with these questions in his *Natural History and Geography of the Antarctic Krill*. He shows that the krill population is maintained principally by spawning on or near the Antarctic coastal shelf, where the current follows the prevailing east wind. The west-wind zone farther north has relatively few krill except where there is a marked northerly outflow of water from high latitudes, the great exception being in the Atlantic sector, where the west-wind zone, being fed by a massive outflow from the Weddell Sea, is the area where krill is most abundant. It is there that they are largest and most numerous, the whales fattest and the oil of highest quality. But this area of great abundance is not a successful spawning area. Female krill ready to spawn are taken in the nets and found in the stomachs of whales, and krill eggs can be collected by keeping the gravid females alive in a tank until they spawn, but very few eggs, nothing like enough to support a population, are taken from the sea. Study of the vertical distribution of krill larvae in the ocean shows that krill eggs hatch at great depths, probably below 2,000 m if the water is deep enough, and the hatched larvae rise stage-by-stage, reaching the surface as first Calyptopis larvae. This developmental ascent is seen to take place successfully near the Antarctic shelf, but not in the west-wind drift, and the rich population east of South Georgia is seen to be maintained not by eggs hatched locally but by larvae rising from the Weddell drift which brings them from successful hatching regions farther south. What happens to the eggs laid in the rich east Atlantic sector—whether they are carried back to the south, or lost to the north—remains a mystery.

It was to be expected that such remarkable conclusions would cause a stir, and Marr was extremely careful about putting forward all points of view, and very thorough in

reasoning those which seemed to him best to fit the evidence. His conclusions are based on an unprecedented number of observations, an enormous collection of all stages in the life-history, copious field notes on habits and behaviour, counts, measurements, sex determinations, and information on developmental conditions to which most *Discovery* scientists had contributed over 25 years. It has a very wide coverage in place, time and depth, though not so critically distributed as it could be now that the work is done. No one is likely to collect as much again; but we can now see what to do next, where to look and what to look for. To have made this possible is a very great achievement since the krill occupies a supreme position in the economy of the Antarctic seas.

Marr wrote a fascinating account of the history of the South Orkney Islands, and of the scientific work done during the *Discovery's* survey of the group, taking great pains to give a clear account of what earlier explorers had done. His collecting was done with tremendous enthusiasm and he spared no effort in recording and preserving the material. He wrote on the preservation of marine animals and was so outstandingly successful in collecting and keeping them in good condition that visitors to the ship, whether eminent scientists or gracious Commonwealth Governors, were always charmed with what they saw. His last major work was on the natural history and distribution of the unstalked crinoids of the Antarctic shelf. He always wrote with a zest for his subject that makes it a pleasure to read.

During the Second World War he served in Iceland, the Far East and South Africa, and in 1943 he was given the special task of organizing and commanding land bases in the Grahamland region of Antarctica. He was three times awarded the Polar Medal, and he also received the Bruce Memorial Prize of the Royal Scottish Geographical Society and the Back Grant of the Royal Geographical Society.

Worsley, writing of the voyage in 1925, said Marr was the strongest man on board and their champion at stowing any sail, square or fore and aft. He was a great man. However hard and unpleasant the work, he never spared himself, and his failing health during the past few years was undoubtedly due to the prolonged and exceptional conditions of his work at sea and in the Antarctic. His *Natural History of the Antarctic Krill* is a history and text-book of marine exploration and science as well as a remarkable sum of knowledge and experience of Antarctic biology: an American reviewer has described it as natural history at its best.

G. E. R. DRACON

<sup>1</sup> *Discovery Reports*, 22, 23 (1962).

### Prof. V. F. Hess

THE work during the years 1911 and 1912 of Prof. Victor Hess, who died at the age of eighty-one on December 18, 1964, has been recognized as that which clearly established the extraterrestrial origin of the cosmic radiation, and it was for these investigations that he received the Nobel Prize for Physics in 1936.

Born in Waldstein and educated in Graz, where he took his doctorate in 1910, he worked for some ten years at the Radium Research Institute in Vienna before returning as professor to Graz. In 1931 he was appointed professor and director of the newly founded Institute of Radiology at Innsbruck, and there founded the famous Hafelekar Cosmic Ray Observatory at an altitude of 2,300 m, one of the earliest stations for the continuous observations of cosmic-ray intensity. In 1938, moving to the United States, he took a professorship at Fordham University, which he held until his retirement to an emeritus professorship in 1956. He was a member of the Academy of Sciences at Vienna, of the Pontifical Academy of Sciences in Rome and a Fellow of the American Physical Society.

Before Hess undertook his classical experiments, considerable attention had already been directed to the 'residual ionization' which was always found to be present in the gas of an ionization chamber, and speculation had already turned to the possibility of an extraterrestrial origin. The 'residual ionization' varied remarkably little from one place to another, on the surface and under it, over land and on water, and the absorption recorded when the chamber was surrounded by lead shields was unexpectedly slight. Early attempts to move away from the influence of the condensed Earth by ascending the Eiffel Tower and in the first balloon experiments were inconclusive—partly since the effect is not well marked at the heights of ascent which were reached because of the real attenuation of terrestrial radiation, partly because of inadequate instrumentation.

Hess based his work on a detailed investigation of the absorption of  $\gamma$ -rays in air and, for he was a man of conspicuous experimental ability, on greatly improved ionization chamber techniques using hermetically sealed chambers. In 1911 and 1912 he made a number of balloon ascents, finally reaching a height of 5,300 m. He established that while there was a decrease of ionization with increasing altitude up to about 1,000 m, at greater altitudes the observed intensity of ionization increased so that at 5,000 m it was twice that at the ground. Later work was to exhibit a much more striking increase at still greater heights. Since there was no significant difference in the observations by day and by night, nor, on one occasion, during the short period of a solar eclipse, Hess concluded that the postulated extraterrestrial radiation was not of solar origin.

Although this work and the conclusion which Hess drew from it were to become recognized as sound, they did not at first go unchallenged. This was particularly so because of the confusion which surrounded apparently direct absorption measurements in, for example, water, at a time before there was any understanding of transition effects, and it was not until about 1926 that all doubts about an extraterrestrial origin of the penetrating radiation were resolved.

During his work at Vienna, Hess had already become aware of apparent fluctuations of intensity, and over the succeeding years these were to be the subject of many series of observations by different groups of workers, specific features of which only too often were not supported by subsequent work. The Hafelekar Observatory was set up in 1931, and it played a leading part for many years of sustained and reliable intensity monitoring. In addition to important work in the interpretation of the atmospheric effects (including the identification of the negative temperature effect for which an explanation only became possible some years later), the true solar diurnal variation was established. During this period also, Hess considered that an extremely small sidereal variation had been detected, which might be linked with the Compton-Getting analysis of galactic rotation.

In recent years the main advances in the physics of the cosmic radiation have come from high-altitude and extraterrestrial observations, on one hand, and from an ever-widening range of continuous monitoring systems, on the other. Toward both these areas of investigation Hess was responsible for pioneer work of conspicuous excellence, and his death breaks one of the last links with the earliest observations and the identification of the cosmic radiation.

J. G. WILSON

### Mrs. L. W. Jones

Mrs. L. W. JONES, known to her family and friends as 'Joan', died after a sudden two-day illness at Addenbrooke's Hospital, Cambridge, on June 6. The wife of Mr. Lawrence W. Jones (who is a long-serving executive and director of Pye, Ltd., of Cambridge), she came in

close contact with the radio and electronics industry in the late 1920's. At the outbreak of war in 1939, Mrs. Jones started an engineering shop in the garden of her home as her contribution to the national War effort. She led this operation tirelessly throughout the War years, finding additional premises, plant and personnel to keep pace with Britain's desperate need for radio and radar equipment. 'Labgear' was the name ultimately chosen for this business, because of the nature of its products. When the War was over, Mrs. Jones had to make one of her most difficult decisions, whether to terminate the activity or to continue as a manufacturing business for peace-time requirements. Her sense of adventure and loyalty to the staff who had helped her make such a success of the war-time endeavour soon led her to decide to continue.

The immediate post-war years were difficult ones; it was a period of change. Many new companies were

formed; some succeeded, many failed. However, under the guidance of Mrs. Jones, as its founder-director, Labgear, Ltd., prospered and, from its humble beginnings, to-day employs more than four hundred people and is now a member of the Pye Group of Companies.

Mrs. Jones was loved and respected by her colleagues and every employee of the Company. No one did more to ensure a happy relationship between management and work-people, and she was regarded as a specialist in personnel and production management. Apart from her main business responsibilities she did much to organize welfare and social activities in which she personally participated.

Some five years ago Mr. and Mrs. Jones moved to a country residence and but for Mrs. Jones's untimely death she would have retired from business life this year to enjoy the rewards of her full and active career. Mrs. Jones leaves a widower and two sons who are directors of engineering businesses.

## NEWS and VIEWS

Lord Florey, O.M., F.R.S.

As announced from Buckingham Palace, H.M. the Queen has graciously awarded the Right Hon. Lord Florey the Order of Merit. Lord Florey is president of the Royal Society and provost of Queen's College, Oxford. It has also been announced that Lord Florey is to receive the 1965 John Scott Award from Philadelphia, awarded to "ingenious men who make useful inventions". The award consists of £700, a medal and a citation.

Royal Institution: Sir Lawrence Bragg, O.B.E., F.R.S.

SIR LAWRENCE BRAGG will shortly be retiring from his position as director of the Royal Institution—a post which includes the titles of Fullerton professor of chemistry (held by Sir Lawrence since 1953) and resident professor and director of the Davy Faraday Laboratory (since January 1954). This year also he celebrates the jubilee of the award of the 1915 Nobel Prize for Physics to his father, Sir Henry William Bragg, and himself jointly, for their work on X-rays and crystal structure. Only a few months previously they had been jointly awarded the Bernard Gold Medal of the U.S. National Academy of Sciences, an award made only once in five years (previous recipients having been Ernest Rutherford, William Ramsay and Wilhelm Röntgen). It is interesting to note that W. L. Bragg was only twenty-five years old when these awards were made and that he had studied no physics at school and only a very little in the Honours Mathematics course at the University of Adelaide. His serious study of physics only began when he was twenty and in his second year at the University of Cambridge. Two years later, while still studying, he began that fruitful collaboration in research (mainly in vacations) with his father, which effectively founded the science of the structural analysis of solids. After several years in the Armed Forces during the First World War, he was elected a Fellow of the Royal Society in 1921 and was awarded the Hughes and Royal Medals in 1931 and 1946, respectively. He had been made a Fellow and lecturer in natural sciences at Trinity College, Cambridge, in 1914. After demobilization in 1919, he was appointed Langworthy professor of physics, Victoria University, Manchester, where he built up a famous research school concerned with fundamental problems of X-ray diffraction by crystals, and in particular with the structure of the silicates. In 1937 he became director of the National Physical Laboratory, but in 1938 he left Government service to become for fifteen years Cavendish professor of experimental physics in the University of Cambridge.

Here he resumed his earlier researches into the structure, texture and properties of metals and he became especially interested in the determination of the structure of protein molecules; both these interests he has maintained in directing the work of the Davy Faraday Research Laboratories.

As resident professor of the Royal Institution he has introduced several brilliantly successful innovations. The popularity of the Christmas Lectures for children, a set of which he himself had given in 1934–35, persuaded him that fourth-, fifth- and sixth-form scholars would benefit by having similar courses throughout the year. These could be aimed at a more homogeneous audience and illustrated by demonstrations involving apparatus too large or too costly for school resources. Many thousands of young people have now been interested and inspired by such Royal Institution lectures. Other schemes have involved science teachers and classically trained Civil Servants. While the subjects of the Friday Evening Discourses have been broadened somewhat in interest, the social side of the Royal Institution has also been extended, a responsibility very fully shared by his distinguished wife, and by the presidents of the Royal Institution under whom he has served, the late Lord Brabazon and the present president, Lord Fleck.

Prof. G. Porter, F.R.S.

PROF. G. PORTER has been appointed to the directorship of the Royal Institution in succession to Sir Lawrence Bragg. After graduation from the University of Leeds, where he was Aikroyd Scholar, Prof. Porter served in the Royal Navy in the Western Approaches. He then went to Cambridge, and pioneered the technique of flash photolysis for which he received his Ph.D. in 1949. He then became a demonstrator in physical chemistry in the University of Cambridge, and was made an assistant director of research and a Fellow of Emmanuel College in 1952. In 1954 he joined the British Rayon Research Association as assistant director. He was appointed to the newly created chair of physical chemistry in the University of Sheffield in 1955, and became Firth professor and head of the Department of Chemistry in 1963. Prof. Porter has received world-wide recognition for his researches into free radical spectroscopy, chemical kinetics, energy transfer, and the physical and chemical properties of aromatic molecules in triplet states. He was awarded the Corday-Morgan Medal in 1955, was Tilden Lecturer of the Chemical Society in 1958–59, was elected to the Royal Society in 1960, was Peter C. Reilly

lecturer of the University of Notre Dame in 1961, and delivered the Remsen Memorial Lecture of the American Chemical Society in 1962. Prof. Porter has a deep interest in scientific education as well as in scientific research, and is well known for his lectures on chemistry to school children. The professorship in chemistry at the Royal Institution was revived for him in 1963, and he has given many lectures in this capacity, both to scientists and non-scientists, while also leading the Department of Chemistry in Sheffield. It is to be hoped that this new appointment will give him the maximum opportunity for the advancement of scientific research and education.

#### National Institute of Agricultural Botany:

##### Establishment of Systematic Botany Branch

A new Branch has been established within the National Institute of Agricultural Botany. This will be known as the 'Systematic Botany Branch' and will consolidate work on the description and identification of plant varieties, which is at present undertaken by Trials and Seed Production Branches. Another function of the new Branch will be to undertake tests on new plant varieties which are required under the Plant Varieties and Seeds Act, 1964. The Branch will form part of the Variety Classification Unit of the Plant Variety Rights Office and will provide information on varieties which have been submitted either for a grant of rights or for inclusion on the Index of Varieties. The Branch will also supply the rest of the Institute with information about the identification of varieties. This information will be particularly valuable in the planning of future trials to test the merits of varieties, and later for the purpose of the various seed certification and seed crop approval schemes.

##### Mr. A. F. Kelly

The first head of the new Branch will be Mr. A. F. Kelly, who is transferring from his present post of head of Seed Production Branch. Mr. Kelly has been at the Institute since June 1945, when he assisted with the establishment and recording of the renewed programme of variety trials after the Second World War. Later he was in charge of the Institute's seed multiplication work and the production of basic seed of varieties from the official Plant Breeding Stations from 1947 until 1954. In 1954 he was seconded to the Organization for European Economic Co-operation for two years to assist in the development of variety trials of grasses and clovers, and of an international agreement on seed certification methods.

##### Mr. G. Finch

Mr. G. Finch, who has been appointed acting head of Seed Production Branch, is probably better known to vegetable growers than to farmers in general. He joined the National Institute of Agricultural Botany in 1948 and has been specially concerned with the development of trials on varieties of vegetables throughout England and Wales. In his earlier years at the Institute he was responsible for the seed production side of the work as well as the variety trials and is consequently well known to most producers of root and vegetable seeds.

#### The Shirley Institute

After forty years at Shirley Institute, Mr. L. H. C. Tippett and Mr. W. A. Richardson retired at the end of June. Both joined the staff on the same day and have seen the Institute grow from small beginnings to an organization with world-wide reputation.

##### Mr. L. H. C. Tippett

Mr. L. H. C. Tippett, assistant director in charge of physics and mechanical processing since 1951, has become internationally known for his work on operational research and statistics. He was a pioneer in the statistical investi-

gation of process operations in the textile industry. He has served on numerous committees concerned with statistics and allied topics. He was the first chairman of the Committee of Statistics in Industry and Technology of the International Statistical Institute and also the first chairman of the Textile Institute's Quality Control Group. He is now president of the Royal Statistical Society. During the course of his career he has received a number of awards for his work, including the Guy Medal in Silver of the Royal Statistical Society and the Textile Institute's Warner Medal. In 1962 the American Society of Quality Control presented him with its Shewhart Medal for "his outstanding leadership in the field of modern quality control".

##### Mr. W. A. Richardson

The other member of staff retiring is Mr. W. A. Richardson, whose work as a senior finishing liaison officer since 1953 has brought him into contact with many people in the industry. During the first twenty years of his Institute career his research work on starch resulted in a notable contribution to the technology of warp sizing. From 1943 until 1958 he was head of the Rayon Department and became concerned in the ever-widening field of man-made fibre processing. He has served on several international and Textile Institute committees concerned with the standardization of chemical methods to analysis of fibre mixtures.

#### Royal Society Research Appointments

THE Royal Society has announced the following appointments to fellowships, dated from October 1, for two years in the first instance: *A Mr. and Mrs. John Jaffé Donation research fellowship*, to Dr. R. F. Griffin to enable him to continue his work on (i) direct photoelectric measurement of stellar radial velocities, (ii) photometric surveys of stellar spectra at high resolution at the Observatories, University of Cambridge; *The Mackinnon research studentship*, to Dr. P. E. Baker to enable him to carry out studies on volcanological and petrological investigations on island-arc and mid-ocean ridges at the Department of Geology and Mineralogy, University of Oxford; *A Stohert research fellowship*, to Dr. C. L. Nobbs to enable him to continue his work on the determination of the mode of attachment of oxygen to myoglobin of the sperm whale at the Medical Research Council Laboratory of Molecular Biology, Cambridge.

The first Bruno Mendel travelling fellowship has been awarded to Dr. R. Whittam, of the Department of Biochemistry, University of Oxford, to enable him to work in the Department of Biophysics of the Weizmann Institute, Rehovoth, during the academic year 1965-66. This appointment has been established with a gift from Mrs. Hertha Mendel to enable a travelling fellowship to be awarded in successive years to British, Dutch and Israeli candidates to enable them to work abroad in the United Kingdom, The Netherlands or Israel.

#### Medical Research Council

THE Secretary of State for Education and Science, Mr. A. Croxall, in consultation with the Medical Research Council and the President of the Royal Society, has appointed the following to the Medical Research Council from October 1: Prof. D. G. Evans, Department of Bacteriology and Immunology, London School of Hygiene and Tropical Medicine; Prof. W. Melville Arnott, Department of Medicine, University of Birmingham; Prof. J. L. Gowans, Henry Dale professor of the Royal Society, Department of Pathology, University of Oxford. These members have been appointed in succession to Prof. M. M. Swann, who resigned from the membership of the Council on his appointment to the Council for Scientific Policy, and to Prof. Wilson Smith and Prof. M. L. Rosenheim, who are retiring on completion of their term of office.

## Advisory Committee for Scientific and Technical Information

THE Secretary of State for Education and Science has appointed the following to the Advisory Committee for Scientific and Technical Information, the setting up of which he announced in the House of Commons on April 27 (*Nature*, 206, 685, 1965; 207, 234, 1965): Sir James Cook, Vice-Chancellor, University of Exeter (chairman); Dr. N. F. Astbury, director, British Ceramic Research Association; Dr. J. W. Barrett, research director, Monsanto Chemicals, Ltd.; Prof. J. D. Bernal, professor of physics and of crystallography, Birkbeck College, University of London; Dr. G. M. Dyson, consultant; Prof. S. Gill, professor of computing science, Imperial College of Science and Technology, London; Prof. S. P. Hutton, head of Mechanical Engineering Department, University College of South Wales and Monmouthshire, Cardiff; Dr. R. M. Lodge, research manager, Imperial Chemical Industries Fabrics, Ltd.; Prof. G. A. Smart, professor of medicine, University of Newcastle upon Tyne; Mr. B. C. Vickery, librarian, Manchester College of Science and Technology.

## Mond Chemical Products

THE name 'Mond' has become so closely associated with nickel as to be practically synonymous. We think of Mond nickel in terms of various types of nickel steel production, nickel crucibles, tubes, modern coinage, 'nichrome' electric resistance furnaces and heaters, etc., but the diverse applications of this metal in the form of oxides and salts are perhaps not so generally appreciated and do not necessarily recall the name 'Mond' in this particular context. If such omission has indeed existed, it has now been well and truly repaired by the recent issue of a booklet entitled *Mond Chemical Products* (Pp. 10. London: International Nickel Co. (Mond), Ltd., 1965). Apart from nickel oxide and its salts, the 'Mond' range of compounds summarized in this publication includes cobalt oxides and salts, selenium compounds and tellurium. In an accompanying Press release note it is stated that: "Mond chemicals . . . are used in one form or another in such differing places as the kitchen and the paint pot, the machine shop and the farm, the plating shop and the pottery". This great range of uses obviously implies a common factor, namely, a high degree of uniformity and purity in the several chemicals themselves. In this booklet each of the commonly available compounds of nickel, cobalt, selenium, and the tellurium product, are described under the headings: product and formula, approximate content of nickel, cobalt, etc., appearance (form and colour), trade in which used, and purpose of such use; it is in the last category that the wide use of these chemicals is realized. Nickel compounds find uses as alloy additions, active materials for storage batteries, catalysts, colours, fungicides, plating solutions, etc.; cobalt oxides and salts are used as catalysts, colours, for correcting cobalt deficiency in farming, driers, moisture indicators and mordants; selenium compounds are used as colours, catalysts, decolorizers, electrical rectifiers, oxidizing agents, stainless steel, etc., tellurium finds its chief use in the metal industries as an addition element for machinability or, in the case of cast iron, as a carbide stabilizer. A short list of publications dealing with the use of these 'Mond' chemical products, and a list covering world-wide distributors of them, complete the useful data to be found in this booklet.

## The Albright and Wilson Group

THE name of Albright and Wilson has long been associated with the manufacture and marketing of phosphates on a world-wide scale, but in the past few years there have been some major changes in product range, brought about partly by the absorption of other manufacturing companies concerned with both fine and heavy chemicals. To-day, the Albright and Wilson Group

embraces more than thirty-five companies operating predominantly in the chemical field; it manufactures in eleven countries, employs about 11,000 personnel, commands assets now exceeding £45 million, and has a sales turnover of more than £80 million. To bring the public up to date with the present and expanding activities of the Group, there has recently been published a small illustrated brochure which provides a succinct account of its contemporary activities (Pp. 28. London: Albright and Wilson, Ltd., 1965). Detergent and shampoo raw materials have, according to this booklet, been the greatest single factor in the growth of Albright and Wilson during the past fifteen years, because heavy-duty powder detergents contain at least a third by weight of sodium tripolyphosphate as an essential water-softening and dirt-disposal agent. Marchon Products, Ltd., joined the Group in 1955 and this led to further contributions to detergents, notably surface-active agents such as alkyl aryl sulphates, fatty alcohol sulphates, and other specialized ancillaries such as hydrotropes and foam stabilizers. The Group is one of the leading world suppliers of shampoo raw materials for hair-washing, car and carpet shampoos. In the field of fertilizers, insecticides and herbicides, the Group is strongly established; a plant at Port Maitland, Ontario, has an output of 275,000 tons of single and triple superphosphate, phosphatic solutions and feed-grade dicalcium phosphate. Thiophosphates, long made by Albright and Wilson for insecticides, continue in demand, but with the recent addition to the Group of Stafford Allen and Sons, Ltd., the range is now supplemented with the important pyrethrum and derris extracts. Sodium chlorate continues as a weed killer, but the tendency is now towards the use of organic herbicides such as ammonium sulphamate; for fungicides and bactericides, organo-tin chemicals manufactured by the Group (for example, tributyl tin oxide) are of increasing importance. Another important field concerns flavours and fruit extracts, involving production of essences, essential oils, juice compounds, and powders; spices are included. Fruit juices, extracts and concentrates are produced by the Group in eight countries, the most important being derived from lemons and oranges. Other interests lie in metal-finishing chemicals and processes, manufacture of perfumery and cosmetic products, pharmaceutical products, plastics and paint chemicals, silicones, sodium chlorate and paper products. The brochure concludes with brief notes on other products of the Group, on sales and marketing organizations of the member companies, technical service, research and development, and on the work of its engineering departments responsible for design and construction of most of the new plants and factories required.

## City of Gloucester Museums

THE report of the City of Gloucester Museums for the year ended March 31, 1964, issued in an attractive format, gives some idea of the extremely munificent bequest received under the will of the late Mr. Samuel Stanley Marling (Pp. 16+4 plates. Gloucester: The Museums, 1965). It comprised eighteenth-century furniture, English domestic silver, Bristol and Nailsea glass, period barometers, clocks and watches, early trees, English gold coins, and eleven oil-paintings attributed to Richard Wilson (1713-82). Outstanding objects include an ivory-cased stick barometer by Daniel Quare (1648-1724), a month long-case clock by Christopher Pinchbeck (1670-1732), and an exceptionally fine silver-gilt inkstand in the form of a celestial globe, made by John Robbins in 1792. A token exhibition of the bequest was staged in 1963, but the remainder must await the building of two additional galleries as extensions to the City Museum. These will be constructed over the present single-storey section of the Brunswick Road buildings. Six further cabinets have been constructed to house the herbarium, and the Upton Collection of land and freshwater molluscs has been

re-catalogued. Ten type specimens of fossil brachiopoda and a crushed specimen of *Liparoceras cheltonae* from the lower Lias of Battledown Brickworks, Cheltenham, have been transferred to the British Museum (Natural History).

#### City Museum, Sheffield

THE annual report of this progressive Museum for 1963-64 records that work has commenced on the long-term project of compiling a card-index of all published references to the natural history of the Sheffield region (Pp. 23+8 plates. Sheffield: The City Museum, 1965). Even in its early stages it is proving valuable to the Museum staff in dealing with enquiries, and eventually it should prove equally valuable to research workers and members of local societies. An unusual feature in an annual report is a chronological survey of table cutlery. The compendium covers the typology of cutlery, especially knives, from the tenth to the twentieth century. It is fully illustrated and the dating will be of interest for its own sake and for the light which it may shed on the date of associated items or structures. Sometimes, an estimate of the date of manufacture of a knife which is featured in a painting or drawing may assist in determining the age of the picture. Likewise, the representations of knives sometimes found carved on wood or stone, engraved on metal, painted on ceramics or even embroidered on textiles, may help to date the objects themselves.

#### Serotine Bats

THE Earl of Cranbrook has reported that, during late June, serotine bats were observed to be moving in a more or less discrete group up and down a two-mile stretch of road and feeding on summer chafers (*Transactions of the Suffolk Naturalists' Society*, 13, Part 1; February 1965). A small number were captured in mist nets. When in pursuit of their prey the bats showed a remarkable facility in avoiding the relatively dense motor traffic along the road; no casualties were observed. All the bats captured were lactating females, although they were identifiable as juveniles by weight and tooth wear. A few noctules flew with the serotines in pursuit of the same prey. The serotines seemed to be affected more by the weather than were the noctules.

#### Fruit and Vegetable Dehydration

Among the methods of preserving and processing food, that of dehydration occupies an important position. It turned out to be particularly valuable during the Second World War, and there was an outburst of technical and scientific activity to cope with the demands at that time. After a post-war recession of interest in dehydrated products, they are now one of the most rapidly developing sections in the field of food technology. A good deal of this is due to the pioneering work carried out at the Ministry of Agriculture, Fisheries and Food factory at Aberdeen, especially in developing methods of freeze-drying of foods. The publication of *The Dehydration of Fruits and Vegetables—A Review of Methods*, by L. P. Hall, is to be welcomed; this is published as *Technical Bulletin* No. 9 by the Fruit and Vegetable Canning and Quick-Freezing Research Association, Chipping Campden. (The word "Dehydration" could now well be included in their name, or perhaps "Processing" could be substituted for Canning, Quick-Freezing, and Dehydration.) This is a short and competently written survey of existing methods of dehydration. It is sufficiently up to date and comprehensive to include tumbling freeze-drying, as well as fluid-bed and belt-trough drying; and explosion puffing as a means of pre-heating foods to speed up the actual drying process. The excellent descriptions in the booklet (Pp. 16) might have been shortened and improved by a number of diagrams showing the principles of the various processes. There are useful sections on bacteriological and nutritional aspects of dehydrated fruits and vegetables. The review as a whole is a model of brevity and clarity, and will be a

useful short guide to the subject even after a fuller and more comprehensive account of dehydration methods has been produced.

#### Descriptions of Pathogenic Fungi and Bacteria

THE Commonwealth Mycological Institute, Kew, began in 1964 to issue a series of loose-leaf sheets "to provide standard descriptions of pathogens for use by pathologists, particularly those isolated workers with restricted library facilities". These have now reached a very substantial volume of six sets of ten sheets each (price 5s. per set, post free) and it is obvious that they fill a long-felt want not particularly related to restricted library facilities. The first set, moreover, dealt with ten rust diseases of warm region crops, but subsequent sets have described pathogens found over a much wider range of climate. Set 2 considered ten bacterial diseases; Set 3, *Fusarium* spp.; Set 4, *Phytophthora* and *Pythium* spp.; Set 5, another ten bacteria; and Set 6, rust diseases of temperate and tropical crops. Workers at the Institute seem to have selected for description pathogens which present some difficulty in practice, and their treatment is invariably concise yet comprehensive. Each pathogen is described in detail, with cultural information where applicable, with host range, symptoms, geographical distribution, references to literature and most useful miscellaneous notes. Descriptions of fungi are illustrated by at least two half-tone illustrations which are excellent for the purpose. These sheets save much time in the day-to-day diagnosis of plant pathogens and have a remarkably wide application.

#### Development and Genetics in Higher Plants

THE success of modern research is very dependent on the choice of a suitable experimental material, especially in the field of development and genetics in higher plants. In this respect the small annual cruciferous plant *Arabidopsis thaliana* (L.) Heynh. has many advantages, for example, high variability in natural habitats, little space requirement, low demands in culture, rapid generation succession, abundant seed production, readiness for experimental hybridization and autogamy, a polymorphic spectrum of induced mutations, vigorous growth in sterile culture, availability of clear phenotypic marker genes and low chromosome number. Therefore in the past decade *Arabidopsis* has gained special attention as a model plant in laboratories throughout the world. This fact was confirmed at the first international symposium on "Arabidopsis Research", held in Göttingen during April 21-24. The symposium was arranged in five sessions: (1) taxonomy and variation (including ecological distribution, interspecific hybridization, polyploidy and embryology); (2) development (genetic control of differentiation and morphogenesis, seed dormancy, vernalization and flowering); (3) genetics (genetic basis of segregation, linkage, non-meiotic recombination and plastom mutation); (4) mutant analysis (isolation and analysis of biochemical mutants, chlorophyll formation and plastid fine structure in leaf colour mutants); (5) mutagenesis (X-ray-induced embryonic malformations, chemical structure of  $M_1$ -plants, heterologous tritiated-DNA- and thymidine-analogue incorporation, induction of recessive lethals and action of various chemical mutagens). The versatility of *Arabidopsis* was thus well demonstrated by this broad spectrum of subjects as well as by some particularly outstanding experimental results, such as the first proof of mitotic recombination in higher plants, or a detailed insight into the mechanisms of vernalization or the pathway of thiamine biosynthesis by means of nutritional mutants. The symposium was especially valuable for the exchange of methods and general experiences dealing with the design of experiments with this 'botanical *Drosophila*'. This was implicit in the twenty-nine papers and the discussions that followed them from the thirty-five

research workers who took part in the symposium. Thus the *Proceedings* of this symposium should serve as a good introductory guide for the utilization of *Arabidopsis* in scientific experiments (they are available from the editor, Dr. G. Röbbelen, Institut für Pflanzenbau und Pflanzenzüchtung, Universität Göttingen, von Sieboldstr. 8, Deutschland).

### Clean Air

THE thirty-first annual Clean Air Conference, sponsored by the National Society for Clean Air, was held at Harrogate during October 20-23, 1964, and the *Proceedings* have recently been published (Pp. 132. London: National Society for Clean Air, 1965. 25s.). The opening address was given by the Rt. Hon. Lord Sheffield, until recently chairman of the Atomic Energy Authority; his benediction was appropriate: "If you want to have cheap power with clean air, go nuclear". Dr. Albert Parker delivered his presidential address, which preceded the opening in the Exhibition Hall of the largest "Clean Air, Fuel Efficiency and Domestic Heating Exhibition" in the Society's history. The subsequent proceedings covered smoke-control area reports from various parts of Britain; papers on the rarely discussed topic of air pollution and town planning; on smokeless fuels—the future supply position. Dr. J. S. Carter gave the Des Vœux Memorial Lecture, entitled "A Century of Achievement, reference the Alkali Act". Another subject discussed was road vehicle pollution, dealing particularly with black smoke, some causes and possible methods of control. The important document concerning the menace of sulphur dioxide, the *Sulphur Dioxide Report*, the work of a special technical committee, as presented by Dr. J. S. G. Burnett, is available as a separate publication; although not included in this volume, the discussion on it followed that on "Road Vehicle Pollution", and is given in detail.

### Announcements

THE fifth International Seaweed Symposium will be held in Dalhousie University during August 25-28. Further information can be obtained from Dr. E. Gordon Young, National Research Council, 1411 Oxford Street, Halifax, Nova Scotia.

THE fourteenth North American Clay Minerals Conference will be held in the University of California during August 23-26. Further information can be obtained from Clay Minerals Conference, Engineering Extension, University of California, Berkeley, California.

THE seventh international conference on "Phenomena in Ionized Gases" will be held in Belgrade during August 22-27. Further information can be obtained from the Seventh International Conference on Phenomena in Ionized Gases, P.O. Box 699, 16/0/IV, Studentski trg, Beograd, Yugoslavia.

THE thirty-eighth congress of the Australian and New Zealand Association for the Advancement of Science will be held in Hobart, Tasmania, during August 16-20. Further information can be obtained from Mr. E. L. Freeman, Science House, 157 Gloucester Street, Sydney, New South Wales.

A SYMPOSIUM on "Insect Behaviour", arranged by the Royal Entomological Society of London, will be held at the Imperial College of Science and Technology during September 23-24. Further information can be obtained from the Registrar, Royal Entomological Society of London, 41 Queen's Gate, London, S.W.7.

AN international symposium on "Microchemical Techniques", organized by the American Microchemical Society, will be held at the Pennsylvania State University during August 22-27. Further information can be obtained from Mr. H. J. Francis, jun., Pennsett Chemicals Corp., 900 First Avenue, King of Prussia, Pennsylvania.

AN international conference on "Luminescence", sponsored by the International Union of Pure and Applied Physics, will be held in Budapest during August 23-30. Further information can be obtained from Dr. G. Szigeti, Research Institute for Technical Physics of the Hungarian Academy of Sciences, Budapest, POB: Ujpest 1.

THE annual meeting of the Plant Phenolics Group of North America will be held in Albany, California, during August 23-25, and will include a symposium on "Phenolic Compounds as Metabolic Regulators". Further information can be obtained from Dr. V. C. Rimeckles, Imperial Tobacco Company of Canada, Ltd., P.O. Box 6500, Montreal, Quebec.

AN international conference on "Electron Diffraction and Crystal Defects", sponsored by the Australian Academy of Sciences, the International Union of Crystallography and the International Union of Pure and Applied Physics, will be held in Melbourne during August 16-21. Further information can be obtained from Dr. R. I. Garrod, Aeronautical Research Laboratories, Box 4331, G.P.O., Melbourne, Victoria.

## GAS CHROMATOGRAPHY

AN informal symposium organized by the Ministry of Technology was held on May 31 at the Paisley College of Technology, Paisley, with Mr. A. F. Williams in the chair. The participants were welcomed on behalf of the College by the principal, H. N. Henry.

The first paper was given by Mr. G. R. Jamieson (Paisley College of Technology) on "Gas-Solid Chromatography using Adsorbents with Modified Surfaces". He first pointed out that the advances in gas-solid chromatography had been much less spectacular than those in gas-liquid chromatography but, during the past two years, an increasing number of investigations using gas-solid chromatography had been reported in the literature. Possibly one of the main reasons for this renewal of interest was that with the advent of sensitive ionization detectors, there was now no major difficulty in operating in the linear range of the adsorption isotherm. He then went on to say that although gas-liquid chromatography was, at the moment, more versatile than gas-solid chromatography, the latter method had two potential advantages: (1) the great potential selectivity of the adsorption process; (2) the sharper resolution that should be attainable and thus the greater speed of separations. Various illustrations of these advantages were given: (1) separation of methylpyridines on alkali metal nitrate columns; (2) separations on various inorganic salt columns operated at 88° C; (3) separations on porous layer glass beads-metal oxide columns; (4) separations of quaterphenyls and hexaphenyls on lithium chloride and caesium chloride columns.

Mr. Jamieson next described some separations which he had carried out on various alumina columns. He showed how the retention indices of benzene and alkenes varied depending on the pretreatment temperature of the alumina, and also how, using small sample sizes, well-shaped peaks were easily obtainable. The effect on the retention indices of the foregoing compounds of modifying the surface of the alumina with different sodium halides was described, and he showed that column characteristics could be altered by changing the anion, by either slurring the alumina with the halide or by mixing dry, and by varying the pretreatment temperature of the alumina before modifying the surface with the halide. The effects of using silica instead of alumina were next described and also the results obtained by butylating the silica.

The final point made by Mr. Jamieson was that the use of liquid crystals as stationary phases offered a field of investigation. Liquid crystals behave mechanically as liquids, but they preserve some of the order of crystalline solids. Taking *p*-azoxyanisole as an example, he said that this compound in the nematic state would be expected to show a selective affinity for linear molecules and on a 4 ft. x 0.25 in. column of *p*-azoxyanisole on 'Celite' he was able to separate the isomeric bromotoluenes, the expected order of emergence, *ortho*, *meta*, *para*, being realized.

Mr. Jamieson then took the chair for the second paper, which was given by Mr. A. F. Williams (Imperial Chemical Industries, Ltd., Nobel Division) on "Techniques for Quantitative Gas Chromatography; the Analysis of Cellulose Ethers and Nitroglycerine". Mr. Williams first discussed quantitative gas chromatography in terms of sample addition, the detector and the use of peak heights or peak areas for calculation of results. The katharometer and flame ionization detectors were considered to be the most widely used detectors for quantitative work in the general field of organic analysis. When the katharometer was used for detection, careful control of the amount of sample going on to the column was essential because the detector is linear only over a limited range of concentration. This degree of control was much more important when

nitrogen was used as carrier gas than when helium or hydrogen was used and also varied with the composition of the sample and its type. It was therefore usually necessary to carry out two determinations if accurate results are required, although this depends to some extent on the nature of the sample. When the flame ionization detector was used, considerably more latitude concerning the amount of load may be taken, although the amount of sample used for analysis is the order of a factor of 100-1,000 times less than that used in conjunction with katharometers. No evidence was obtained to show that the use of peak areas instead of peak heights led to more accurate results. A detailed examination of the results obtained using both types of detector for the analysis of a simple benzene, toluene and xylene mixture has been carried out and the effects of load, using a splitting procedure and changes in electrode gap, were illustrated. It was concluded that the flame ionization detector was more useful than the katharometer for quantitative work.

Mr. Williams concluded his paper by illustrating the application of the flame ionization detector to the analysis of mixtures of nitroglycerine, ethylene glycol dinitrate and nitrotoluenes, and also to the rapid determination of alkoxy groups both in simple ethers and also in cellulose ethers.

A considerable amount of discussion followed Mr. Williams's paper about the relative merits of the use of 'peak heights' and 'peak areas' for quantitative analysis and of the problems which arise in the quantitative analysis of mixtures of biochemical origin when the components can be identified, but no pure standards are available for quantitative calibration purposes.

The third paper was given by Dr. F. L. Mitchell (Royal Infirmary, Edinburgh) on "Gas Chromatography of Radioactive Substances". He said that with the increasing use of radioactive isotopes in chemistry and biochemistry, it is important that such a powerful analytical tool as gas chromatography should incorporate a sensitive device for the detection and measurement of radioactivity. Various techniques have been tried, including scintillation counting of continuously collected zones from the column, and gas-flow proportional counting, working at both column and room temperature.

A technique based on that of James and Piper (1961) has been developed commercially and has proved very satisfactory for the counting of carbon-14 and tritium. Before passing through a gas-flow counter at room temperature, the column effluent is first subjected to oxidation and reduction by passing the gas at 800° over cupric oxide followed by iron filings. The argon then contains only hydrogen and carbon dioxide from the organic material originally present, and 4-5 per cent of dry carbon dioxide is added to the stream to produce a suitable gas for proportional counting. The gas-flow counter consists of a metal tube of approximately 10 ml. capacity with a fine stainless-steel wire stretched longitudinally from end to end. After amplification, the output from the counter is fed to a ratemeter which displays on the recorder either the rate at which the pulses are arriving, or the integral of their total. By using the integrator 5 mpc. can easily be detected and measured. The gas stream from the column may be split, one part passing through the normally used detector while the other is directed through the counter, or the whole may be passed through the counter after passing through a conventional closed detector such as that using argon ionization.

Separation by gas chromatography, with simultaneous detection of the zones by both normal techniques and radioactive measurement, has proved useful to the biochemist in the examination of biosynthetic pathways, to the isotope manufacturer for establishing the purity of

labelled compounds, and to the chemist whenever information on the fate of a particular compound during a complex chemical reaction is required.

Mr. J. Wight (University of Strathclyde) read a paper on "The Examination of Food Volatiles by Gas Chromatography". He said that what we term 'flavour' is a combination of taste, smell or aroma, and the 'feel' of the food in the mouth. Of these the aroma is by far the most important and, since this depends on the presence—usually in minute amounts—of certain volatile compounds, the advantages of gas chromatography in aroma investigations become apparent. There are few gas-chromatographic techniques special to these investigations, and the main difficulties lie with the collection and concentration of the volatiles and with the identification of the components. Where large quantities of food have to be stripped of their volatiles, for example, by distillation, steam or nitrogen stripping, care must be taken to avoid loss or change; high-temperature treatment will almost certainly result in the production of artefacts.

Separation and identification are complicated by the large number of components present, the presence of chemically dissimilar classes of compounds and the wide range of retention times. Use must be made of techniques other than gas chromatography, and recently the mass spectrometer has proved to be a most powerful aid to identification.

There are many distinct applications of gas chromatography, for example, the general study of aroma volatiles, the production of aroma by cooking or processing, the investigation of flavour defects of stored foods and the quality control of materials such as essential oils.

It must be remembered that the results obtained by gas chromatography are essentially analytical and that these results have still to be interpreted in terms of

aroma. In the absence of sufficient data on threshold values both of pure substances and of mixtures, it is important that the analytical work be supported by flavour panels. The aroma as sensed by the nose is, after all, the final criterion. Mr. Wight concluded his paper by showing chromatograms obtained from the volatiles of various common foodstuffs.

The final paper was read by Mr. J. Craig Higgins (National Coal Board) on "Developments in the Technique of Mine Air Analysis by Gas Chromatography". Mr. Higgins first of all pointed out that for the special problems involved in mine air analysis, no commercial gas chromatograph had been found suitable and a gas chromatograph had been designed and constructed at the laboratories of the National Coal Board.

He then went on to give a very full description of this gas chromatograph, which was a dual-column instrument but not in the usual sense of the meaning of dual column. Two different column packings were used, 'Molecular Sieve 5X' and silica gel, and detection was by thermal conductivity cells. By means of a special valve system, samples of the gas to be analysed were put on to both columns simultaneously and flow rates were adjusted so that the components from one column were recorded before the components started to emerge from the second column. In using this system a complete analysis of the mine gas could be recorded on the one chromatogram.

Mr. Higgins ended by showing how these chromatographs were used in the National Coal Board's mobile laboratories, and he pointed out that wherever possible duplication of equipment was essential to obviate any breakdown or failure of components in these mobile laboratories.

The symposium concluded with an address by Mr. A. C. Low of the Ministry of Technology. G. R. JAMIESON

## CNIDARIA AND THEIR EVOLUTION

THE Zoological Society of London organized a symposium during March 3-4, at which evolution in the Cnidaria as well as many diverse aspects of this plastic group were reviewed and discussed.

Opening the symposium, Prof. C. F. A. Pantin (Cambridge) gave a stimulating address on "Homology, Analogy and Chemical Identity". To the first two, he added "chemical identity", that is, resemblances which can be traced to the absolute similarity of each set of isotopes in the Periodic Table and of the molecules built from them. He indicated that chemical identity can give rise to packing phenomena, as in crystals, creating well-defined morphological features, far above the atomic level, which are, or partially only, the result of adaptive selection. The independent appearance of particular classes of molecule such as are found in pigments and other 'chemical building stones' arises from chemical identity. Much caution should therefore be adopted in using features of this kind as evidence of evolutionary relationship.

Prof. Pantin indicated that analogy arises because natural selection operates by setting the organism engineering specifications for each part that must be realized for survival. He regarded the longitudinal musculature of cnidarian polyps as an example of a weak specification allowing many solutions. On the other hand, rigid and detailed specifications like those responsible for close similarities in complex eyes are not evident in the Cnidaria.

Homologies of parts account for the most characteristic resemblances between animals, these homologies depending on a plan or archetype to which the structure of all species in the class may be referred. This archetype (which is not an ancestor) and its homologies he considered as a network of tissue relationships. Further, he thought the system as a whole met an engineering requirement and

that natural selection acted strongly against any serious departure from the network of tissue relationships. However, this network could be distorted to meet the needs of adaptive radiation, and as examples he quoted the different mesenteric patterns of the Anthozoa.

Dr. L. E. R. Picken and Dr. R. J. Skaer (Cambridge) gave a lucid review of researches on nematocytes and dealt comprehensively with the subject. Among other interesting items, the authors discussed a new aspect of nematocyst chemistry—phosphatases, 5-nucleotidase and cholinesterase. Several amino-acid analyses of nematocysts isolated in bulk are now available and something is known of certain other chemical components.

There was also a very interesting demonstration, from electron microscope investigations, that the wall of the undischarged thread in isorhizas of *Corynactis viridis* is pleated to form a triple screw and that the undischarged capsules have a 'notional' osmotic pressure up to approximately 140 atmospheres.

The authors believe that cnidoblasts may still be regarded as independent effectors although the excitation-threshold of the cnidocil-cnidoblast unit may be under nervous control in some instances, depending on the physiological condition of the animal. It also emerged that taxonomic investigations on the different kinds of nematocysts, based on the light microscope, are not enough and that further electron-microscope examinations are essential.

Dr. David Chapman (Halifax, Nova Scotia) developed some interesting ideas regarding the origins of the Scyphozoa from an examination of the anatomy of the scyphistoma of *Aurelia*. He was inclined to regard the fossil conulariids as ancestral to this group, basing his conclusions on certain puzzling features in the anatomy of the scyphistoma which could be explained by adopting

this evolutionary concept. A new notion that mesoderm is found in polyps in the form of a surface epithelium was linked with the formation of podocysts and like structures. Dr. Chapman concluded from the behavioural investigation that the polypoid preceded the medusoid stage in the evolution of the Scyphozoa and further suggested that the scyphopolyp was the simplest cnidarian polyp. The development of the strobila was regarded as an aeration device for developing gametes. Dr. Chapman concluded his paper with a discussion of the modifications of the scyphistoma in the class, in which he regarded the rhizostome scyphistoma as a very simple cnidarian polyp possessing a complex medusa. This would, in effect, be an example of mosaic evolution although Dr. Chapman did not actually call it so.

From a review of the five orders of Scyphozoa, Dr. Hjalmar Thiel (Hamburg) concluded that the scyphozoan stem form was a tetra-radial polyp with four tentacles, four peristomial pits and four septa, which ancestrally also possessed four or eight gonads on the septa. He derived the metagenetic development of the medusa from the transverse fission of the scyphistoma in which the products of the fission were originally daughter polyps evolving by way of a planktonic life into medusae. The Stauromedusae, a group that combines polypoid and medusoid characteristics, he regarded as having originated through the fusion of the two generations (scyphopolyp and medusa), or in other words an arrested metagenetic development.

The interstitial fauna of sandy beaches and sub-littoral sand contains some very interesting forms and among them some minute Hydrozoa. Since Remane described two actinula-like forms which he called *Halammohydra* in 1927, a further two and a new genus, *Otohydra*, have been investigated at Roscoff by Dr. B. Swedmark and Prof. G. Teissier (Kristineberg and Roscoff). In their contribution to this symposium they reviewed these strange forms (combining the characteristics of polyp and medusa, as well as possessing larval features). These they have placed in a new order, the Actinulida. In their comprehensive survey of these aberrant forms, Dr. Swedmark and Prof. Teissier consider that the Actinulida have arisen from an ancestral actinula which colonized the interstitial environment very early on and there acquired statocysts—a type of organ very common in many different organisms in this environment. In other words, vague suggestions made over the years that the Actinulida are reduced Narcomedusae that have adopted an interstitial habitat are rejected, but, in the discussion that followed, Dr. B. Werner indicated his adherence to the older concept. This paper was followed by a film of *Halammohydra* made at Roscoff.

The evolution of the Actiniaria was discussed in a controversial and stimulating paper by Prof. Cadet Hand (California), who was led from an investigation of the puzzling pattern of development of mesenteries, first as couples and later as pairs, to consider the origins of sea anemones. He pointed out that coupling has an adaptive value in preserving symmetry round the mouth axis but that the pairing of mesenteries does not have this significance. However, in contrast to the situation in the madrepores, the pairing of mesenteries was demonstrated to be an adaptive and functional character. Accordingly, Dr. Hand suggested that the Actiniaria have been derived from corals and, furthermore, that the so-called primitive anemones (Athenaria) may be better considered as secondarily derived forms—thus reversing present ideas. From this new hypothesis the thesarian anemones would be the most generalized and most closely related to corals, and from these a course of evolution to the acanthate anemones and to the athenarian forms was traced.

Prof. Garth Chapman (London) reviewed the structure, function and what is known of the origin of the mesogloea. In many species the mesogloea is of a fibrous nature, and, from its amino-acid composition and

X-ray diffraction pattern, may be called a collagen. It was pointed out that the scyphomedusan mesogloea would probably be represented as a simple polymeric gel, whereas the mechanical properties of the actinians may be best represented as a parallel cross-linked and a non-cross-linked polymeric system. It emerged that the functions of the mesogloea are diverse, being neither clear-cut nor uniform, but include acting as antagonist to muscle, flotation and as a possible nutritional reserve.

Dr. Maxwell Braverman (Pittsburgh) reviewed his work with Dr. R. S. Schrandt on the development of the athecate hydroid *Podocoryne cornuta* by culture from single individuals on microscope slides and gave a fascinating account of an attempt (in collaboration with Dr. Robert G. Schrandt, of Los Alamos Scientific Laboratory) to simulate this development on an electronic computer. He demonstrated how the computer generates a relatively complex pattern as a mathematical model of the growing system by the iteration of a set of simple rules of growth. This growth, which consists of a connected network of points in a two-dimensional net, can be followed generation by generation and selected parameters of the generated pattern compared with those of real colonies. Dr. Braverman also suggested that the ability of simple recursive rules to generate complex patterns may mean that genetic instructions of developing systems may be partly of a similar nature. From the discussion that followed it also emerged that the production of reproductive hydranths is stimulated by an increase in the carbon dioxide in the stolons that give rise to them.

The various theories concerning the origin and evolution of the Hydrozoa were discussed by Dr. W. J. Rees (London), who attempted to provide an explanation of the origin of metagenesis (the alternation of a fixed benthic hydroid phase with a free-swimming medusa phase). Many early authorities were disposed to regard the tetra-radial polyp as a basic cnidarian, but this is too specialized an organism. It was suggested that the proto-coelenterate was a gastrula and that the ancestral cnidarian was a fertile actinula. The actinula possesses all the basic features which through radiation could give rise to all three classes. In this way, the adoption of a pelagic habit probably led to the evolution of Trachymedusae with a direct life-cycle (egg-planulae-adult medusa) and to the Narcomedusae also with a direct life cycle. In the latter, however, some forms such as *Peyronia* exhibit the beginnings of a metagenesis, while the Hydromedusae living to-day possess a well-developed metagenesis, even in the most primitive family, the Moerisiidae. In the hydroids and medusae the trend is towards the elaboration of the hydroid and the gradual suppression of the medusa. This trend would not appear to be the other way round, as Huxley would have us believe in his Turbellaria theory of the origin of the Cnidaria.

The mushroom corals (Fungiidae), both recent and fossil, were reviewed by Prof. J. W. Wells (New York), who discussed their present status from the stratigraphic, biogeographic and systematic aspects. It was shown that they well illustrate an evolutionary trend (which is common to most living and extinct zoantharian corals), a tendency towards colonial or polycentric forms from the basic monostomatous condition found in *Fungia*. Prof. Wells, who also provided a key and synopsis of genera (including several new ones), considered that this evolutionary trend in fungiids is in full spate at the present time, whereas in most scleractinian groups it has already reached its full development. *Cycloseris* appeared in the early Tertiary, and by Miocene times the central form *Fungia* had evolved from it. Radiation in *Fungia* gave rise to several sub-genera which by the late Miocene had given rise to simple polystomatous types, and Prof. Wells thought it probable that by the Pleistocene times all eight of the so-called colonial genera had probably

developed, although three of these are so far known only from the Recent.

In his account of pathways of excitation in Otenophora, Dr. G. A. Horridge (St. Andrews) analysed the conducting systems principally in *Beroë* and *Cestum*, referring also to other species he had investigated. He recognized four conducting systems and, without going into details here, concluded that separate conducting systems arise and multiply in primitive nervous systems independently and without the establishment of functional contacts with the neurones of other pathways. This he regarded as a necessary formula for the development of a central nervous system.

M. Yves Bouligand gave a comprehensive review of all known ectoparasitic and endoparasitic copepods associated with Anthozoa. Most of these are ectoparasitic, belonging to the families Asterocheridae and Lichomolgidae and to the Xarifiidae. This third family has numerous species associated with Madreporaria.

All the endoparasitic copepods belong to the family Lamippidae—a family in which the sexes exhibit a marked degree of dimorphism. There is a considerable amount of deformity, but the characteristics of the integument and of the musculature enable the metameric plan to be worked out. The ultrastructures of the cuticle seem to show that this is involved in nutritional functions in several species. Various aspects of host-parasite relations were also discussed.

A contribution from Dr. J. H. Barnes (Cairns, North Queensland) dealt with three species of venomous Cubomedusae; these were: a small and as yet unidentified carybdeid (the cause of the Irukandji sting), *Chiropsalmus quadrigatus* Haeckel and *Chironex fleckeri* Southcott; the last of these being identified as the only lethal form and the probable cause of at least fifty deaths in North Australian waters. *Chironex fleckeri*, probably the most venomous marine invertebrate known, may kill bathers, in cases of massive envenomation, in 3 minutes or less. Dr. Barnes's lucid and comprehensive paper may be regarded as an interim report on present progress in identifying the organisms, on treatment and on investigations in train.

Dr. Elaine Robson (Cambridge) reviewed the evolution of the swimming habit in the Actinaria—a process which she believes originated independently in the Goniactinidae, the Boloceroididae and the Actinostolidae. In all, the swimming reflects the temporary excitation of pacemaker elements in the nervous system, and its evolution in at least three separate groups may partly be attributed to the fundamental properties of the coelenterate neuromuscular system. Dr. Robson suggested that pre-adaptive features such as the presence of well-developed ectodermal neuromuscular elements and weak basilar musculature, in forms that use the tentacles, and of well-developed perieto-basilar muscles in those that bend the column, may be significant. It is further suggested that comparatively minor quantitative changes in neuromuscular

and receptor properties may have far-reaching effects in actinarian behaviour.

Prof. Demarest Davenport (California) reviewed recent progress in the study of cnidarian symbioses, giving a lively account of work on the behaviour, *inter alia*, of the sea anemone *Calliactis* in relation to its normal substratum (shells occupied by hermit crabs). In particular, he discussed the unique sensory discriminatory power of the tentacles of the anemone to recognise the periostracum of the shell. This work (with which Prof. D. M. Ross is also associated) was illustrated towards the end of the meeting by some remarkably revealing colour films of *Calliactis* behaviour and also of the swimming behaviour of *Stomphia* exhibited by Prof. Ross.

The phylogenetic and evolutionary value of skeletal formations in athecate hydroids was discussed by Dr. W. Vervoort (Leiden), who was concerned with the family Solanderiidae. It was demonstrated that the idea of a mesogloal skeleton of the Solanderiidae was no longer tenable and that as in other capitate hydroids the skeleton was ectodermal in origin. Dr. Vervoort also demonstrated that the genus *Rosalinda* should be placed in this family, being able to accept neither Picard's placing of this genus in the Zancleidae nor his concept of "Pteronematoidae" as a super-family. It was also his opinion that too much stress should not be laid on the value of nematocytes in classification without adequate support from morphological evidence.

Growth in the hydroid *Tubularia crocea* L. Agassiz was discussed by Dr. G. O. Mackie (Edmonton, Alberta). This species was cultured for ten weeks at Villefranche in clean sea-water at 14° C; a diet of *Artemia* was found satisfactory. Continuous growth was recorded in both stolons and hydrocauli along with the production of many new hydranths. Dr. Mackie recorded the patterns of growth for an established colony and for settled actinulae. It appears that hydranths retain full regenerative ability, and although shedding of hydranths was seen, most of them were never shed during the period of investigation. Contrary to some prevailing assumptions, there is no evidence that hydranths become senescent, requiring to be replaced periodically. Hydrocauline growth does not depend on such replacements and it was suggested that hydranth shedding is associated with poor water conditions, and that, given favourable ones, hydranths probably live indefinitely. Dr. Mackie's results thus question earlier conclusions that periodic hydranth shedding is a normal feature of the life of *Tubularia*.

M. Jacques Theodor (Banyuls) exhibited a remarkable series of clear underwater photographs of cnidaria which he had photographed *in situ* in the Mediterranean and in the Pacific. There was also a demonstration of living *Stephanoscyphus* polyps by Dr. B. Werner (Heligoland), who had recently returned from a cruise in the German research vessel *Meteor*. W. J. REES

## MECHANISM OF POPULATION INVERSION AT 6149 Å IN THE MERCURY ION LASER

By DR. D. J. DYSON

Valve Department, Ferranti Ltd., Edinburgh

**F**OLLOWING the first report of the mercury ion laser by Bell<sup>1</sup>, several further reports have been published<sup>2-4</sup>. Apart from some tentative suggestions by Bell *et al.*<sup>2</sup> no definite conclusions as to the mechanisms of selective population of the upper laser levels have been put forward. This article describes some results of the observation of the time-variation of the spontaneous emission from the helium-mercury discharge which appear to clarify the

mechanism responsible for excitation of the 6149 Å laser transition in this system.

Fig. 1 shows the intensity, as a function of time, of some spontaneous emission lines from a helium-mercury vapour mixture, following the discharge through it of a condenser of a few hundred picofarads charged to 5–10 kV. These excitation conditions are favourable for laser action at 6149 Å. The 5460 Å line showed a time variation

Fig. 1. Spontaneous emission pulse shapes from a helium-mercury discharge compared with the discharge-current pulse

Fig. 2. Decay curves of the logarithm of the 6149 Å emission intensity for a series of temperatures

typical of most of the HgI lines, and the 5677 Å line, which is also a laser line under suitable conditions, showed a time variation typical of most HgII lines. The 6149 Å line, and lines cascading from this, were unique in showing a smooth decay following an initial rapid rise during the relatively short current pulse.

The decay rate characterized by the decaying edge of the 6149 Å emission pulse was found to be sensitive to the discharge tube temperature, controlling the mercury vapour pressure, rather than to the helium pressure. Fig. 2 shows plots of the logarithm of the emission intensity as a function of time for a series of temperatures, the curves having been normalized to the same initial intensity. These measurements were taken with a discharge tube of 2.3 cm internal diameter and of approximately 1 m in length. The discharge condenser was 1,000 picofarads and the charging voltage 8 kV. The helium pressure was about 5 torrs. A mercury pool, with a continuous arc running to a nearby auxiliary anode, formed the cathode. In making the measurements care was taken to observe only emission from the near-end of the discharge tube so as to avoid distortion effects due to the finite optical gain.

The curves shown in Fig. 2 are characteristic of what would be observed if the 6149 Å emission resulted from excitation of the mercury ground-state atom by collision with some excited species formed during the discharge. Writing the concentration of this excited species as  $x$ , and the concentration of the mercury ground-state atoms as  $y$ , then the intensity of the emission at any instant is,

neglecting the small effect of the temperature on the diffusion velocities, proportional to  $xy$ , the product of the concentrations. If  $y$  is predominant, it can be considered to be approximately constant throughout the emission time, and the emission intensity is proportional to  $x$ . The rate of decay of the logarithm of the intensity is therefore

$$\frac{d}{dt} \log_{10} x = \frac{1}{2.303} \frac{1}{x} \cdot \frac{dx}{dt}$$

$$\text{If:} \quad \frac{dx}{dt} = -(k_1 xy + k_2 x)$$

where  $k_1 xy$  represents the rate of disappearance of  $x$  due to collisions with mercury atoms, and  $k_2 x$  the rate of disappearance of  $x$  in the absence of mercury atoms, then:

$$\frac{d}{dt} \log_{10} x = \frac{-1}{2.303} (k_1 y + k_2) \quad (1)$$

The curves A and B of Fig. 3 are plots of the slopes of the curves in Fig. 2 against the corresponding mercury atom concentration  $y$ , taken at times of 2 μsec and 15 μsec respectively. They are approximately in agreement with equation (1) if  $k_2$  is made time-dependent.

If the initial value of  $x$  were independent of  $y$ , then it would also be expected that the initial intensity of the emission would be proportional to  $y$ . Fig. 4 shows a logarithmic plot of the initial intensity against  $y$ . Approximate proportionality is obtained for the lower values of  $y$  where the effect of this on the initial value of  $x$  would be least.

The curve C of Fig. 3 was obtained in the same way as curve A, but using a discharge capacity of 500 picofarads

Fig. 3. Decay rate of the 6149 Å emission as a function of the mercury atom concentration

Fig. 4. Initial intensity of the 6149 Å emission as a function of the mercury atom concentration

rather than 1,000. The slope is the same as that of curve A, which shows that the destruction rate of  $\alpha$  due to the mercury vapour is not dependent on the discharge energy, and is therefore not associated with some excited state of the mercury atom, such as a metastable level or the ion, formed by the discharge.

The only excited species capable of raising the ground-state mercury atom to the upper level of the 6149 Å transition is the helium ion. This interpretation is also consistent with the observed time-dependence of  $k_2$  of equation (1), since the rate of loss by ambipolar diffusion is a function of the electron temperature, and the rate of loss by ion-recombination is a function both of the electron temperature and of the electron density.

The laser action at 6149 Å must, therefore, be due to the process:

where  $\text{Hg}^{+*}$  denotes the  $5d^{10}(1S) 7p3/2$  level of  $\text{HgII}$ , the upper level of the laser transition. The cross-section for this process (derived from the slope of the curves in Fig. 3) is  $1.3 \times 10^{-14} \text{ cm}^2$ .

## EFFECT OF ROTATION ON THE STABILITY OF VERY MASSIVE STARS

By IAN W. ROXBURGH\*

High Altitude Observatory, Boulder, Colorado

IT is now well established that a spherically symmetric massive star, of order  $10^4 - 10^5 M_\odot$ , becomes unstable before the central temperature has risen to the  $6 \times 10^7$  °K needed for nuclear reactions to provide the energy which is radiated away. An approximate analysis of Fowler's<sup>1</sup> gives the same results as detailed investigations by Chandrasekhar<sup>2</sup>, so I shall here follow the approximate method of Fowler to examine the effect of rotation on the stability of massive objects.

With masses of order  $10^4 - 10^5 M_\odot$ , radiation pressure is much greater than gas pressure, the star is convectively unstable, and the structure of the star is that of a polytrope of index  $n$ , where  $n$  approaches 3 as the ratio of specific heats,  $\Gamma$ , approaches  $4/3$ . The virial theorem applied to such a system gives:

$$3(\Gamma - 1)U - \Omega = 0 \quad (1)$$

where  $U$  is the internal energy and  $\Omega$  the gravitational binding energy, reckoned as a positive quantity. With radiation pressure dominant we have<sup>3</sup>:

$$\Gamma = \frac{4}{3} + \frac{\beta}{6} \quad (2)$$

where  $\beta$  is the ratio of gas pressure to total pressure. The total energy of the star is then:

$$E = U - \Omega = -\frac{\beta}{2} U \simeq -\frac{\beta}{2} \Omega \quad (3)$$

As  $\beta \rightarrow 0$ ,  $E \rightarrow 0$ , and the classical massive star approaches neutral equilibrium. For massive object  $\beta$  is given by Eddington's equation<sup>4</sup> which approximates to:

$$\beta = 8.6 \left( \frac{M_\odot}{M} \right)^{1/3} \quad (4)$$

When general relativistic effects are included equation (3) for the total energy is replaced by:

$$E = -\frac{38}{4} \frac{GM^2}{R} + 5.1 \frac{G^2 M^3}{R^2 c^2} \quad (5)$$

where we have substituted for  $\Omega$  the value for a polytrope of index 3, and the extra term is the leading relativistic correction as given by Fowler<sup>1</sup>. As the star contracts the energy will ultimately become positive and the star will then be unstable. In fact, the instability occurs as soon as  $\partial E / \partial R < 0$  as the star is then unstable against contraction; instability will therefore occur for any radius less than:

$$R_I = 5.1 \left( \frac{2GM}{c^2} \right) \frac{4}{3\beta} \simeq 0.8 R_g \left( \frac{M}{M_\odot} \right)^{1/3} \quad (6)$$

where  $R_g$  is the Schwarzschild radius. (This formula is only valid for  $M \gg M_\odot$ .)

If we neglect relativistic effects for the moment, the star would contract, drawing on its internal energy to provide the luminosity, until the central temperature reaches  $6 \times 10^7$  °K when nuclear reactions will provide the energy. The radius of the star can then be calculated from stellar structure theory, and is<sup>4</sup>:

$$R_{MS} \simeq 10^{11} \left( \frac{M}{M_\odot} \right)^{1/3} \simeq 5 \times 10^4 R_g \left( \frac{M_\odot}{M} \right)^{1/3} \quad (7)$$

The star will only reach this hydrogen burning stage if  $R_{MS} > R_I$  and this gives:

$$\left( \frac{M}{M_\odot} \right) < 6 \times 10^4 \quad (8)$$

None of the massive objects with  $M \gg 10^4 M_\odot$  will achieve an equilibrium configuration where hydrogen burning at the centre balances the energy loss by radiation.

During the stable contraction phase, the luminosity of the star is given by the surface boundary condition as<sup>4</sup>:

$$L = 2 \times 10^{34} \left( \frac{M}{M_\odot} \right) \text{ ergs sec}^{-1} \quad (9)$$

This energy loss is balanced by the change of the total energy of the star. If the time required for the star to contract from a very large radius to the radius of instability is  $\tau$ , we have:

$$L\tau = -E = \frac{38GM^2}{8R_I} \sim 2 \times M_\odot c^2 \quad (10)$$

giving a contraction time:

$$\tau = 2 \times 10^{14} \left( \frac{M_\odot}{M} \right) \text{ sec} \quad (11)$$

This contraction time is only of order 10 years for  $M = 10^5 M_\odot$ , and is much shorter than the estimated life-time of the optical phase of radio stars which is some  $10^4 - 10^6$  years<sup>5</sup>.

The estimated life-time of the optical phase of radio stars is of the same order as the nuclear time-scale of hydrogen burning, and if we could find an effect which would stabilize the star we could call on the theory of massive stars, as proposed by Hoyle and Fowler<sup>6</sup>, to explain this optical emission. One such effect is rotation.

The primary effect of rotation is that the classical polytrope  $n = 3$  is stable when rotation is included. This is quite easy to see. The virial theorem for a gas with motion, but in a steady state, is:

$$3(\Gamma - 1)U - \Omega + 2T = 0 \quad (12)$$

\* On leave of absence from the Department of Mathematics, King's College, University of London.

where  $T$  is the kinetic energy,  $\Omega$  the gravitational energy (reckoned positive) and  $U$  the internal energy. For  $\Gamma = 4/3$ , a polytrope of index 3, the total energy is:

$$E = U - \Omega + T = -T < 0 \quad (13)$$

The system is therefore stable. With radiation pressure dominant we have:

$$\Gamma = \beta + \frac{(4 - 3\beta)(\gamma - 1)}{\beta + 12(\gamma - 1)(1 - \beta)} \simeq \frac{4}{3} + \frac{\beta}{6} \quad (14)$$

since  $\gamma = 5/3$  for stars. The total energy is then:

$$E = -\frac{\beta}{2} U - T < 0 \quad (15)$$

The reason that the total energy is now negative definite, even when  $\beta \rightarrow 0$ , is that the contribution of the rotational distortion terms to the gravitational energy, and the decrease of internal energy due to reduced pressure force, more than compensate for the added kinetic energy term.

So far as order of magnitude estimates are concerned since  $\beta$  is small, the  $U$  in equation (15) can be replaced by the unperturbed value,  $U_0$ , and the binding energy is then:

$$E = -\frac{3\beta}{4} \frac{GM^2}{R} - \frac{1}{2} I \omega^2 \quad (16)$$

where  $I$  is the moment of inertia and  $\omega$  the angular velocity. The moment of inertia can be evaluated from the theory of rotating polytropes, and for uniformly rotating polytrope of index 3, rotating with maximum possible speed (centrifugal force balancing gravity at the surface) we have:

$$E = -\frac{3\beta}{4} \frac{GM^2}{R} - 0.02 \frac{GM^2}{R} \quad (17)$$

where the number of 0.02 comes from a detailed investigation of rotating polytropes<sup>1</sup>. For massive stars  $\beta \sim 10^{-3}$  and the energy is decreased by a factor of order 30.

The stability of the objects when general relativity is included is now changed. As the rotation will only be a slight perturbation over most of the star, we can neglect rotational effects in the relativistic correction, so that the total energy is:

$$E = -\frac{3\beta}{4} \frac{GM^2}{R} - 0.02 \frac{GM^2}{R} + 5.1 \frac{GM^2}{R} \left( \frac{GM}{Rc^2} \right) \quad (18)$$

The massive star will become unstable when  $\partial E / \partial R = 0$  which gives:

$$R_I \simeq 250 R_g \quad (19)$$

independent of the mass of the object provided  $\beta$  is small.

Now the radius of main sequence massive objects is given from the structure of the star as<sup>2</sup>:

$$R_{MS} = 1.5 \times 10^{11} \left( \frac{M}{M_\odot} \right)^{1/3} \text{ cm} \quad (20)$$

This is slightly larger than the non-rotating value due to the expansion of the equatorial regions by the centrifugal force<sup>3</sup>. In terms of the Schwarzschild radius, this is:

$$R_{MS} = 7.5 \times 10^3 R_g \left( \frac{M}{M_\odot} \right)^{-1/3} \quad (21)$$

Hence we have:

$$\frac{R_{MS}}{R_I} = 3 \times 10^3 \left( \frac{M}{M_\odot} \right)^{-1/3} \quad (22)$$

This brings the instability right into the interesting region where  $M \simeq 10^3 M_\odot$ . Stars smaller than this can reach the main sequence configuration, burn hydrogen and then collapse.

The rotation will also affect the time-scale of the Hayashi type evolution prior to hydrogen burning or gravitational collapse. With a luminosity:

$$L \sim 5 \times 10^4 \left( \frac{M}{M_\odot} \right) L_\odot \quad (23)$$

which draws on the internal energy, the time required to contract to the radius of instability,  $\tau$ , satisfies:

$$L\tau = -E = \frac{1}{100} \frac{GM^2}{R_I} \quad (24)$$

which gives:

$$\tau \simeq 10^4 \text{ years} \quad (25)$$

for any mass. This estimate is not accurate, as we have neglected the energy carried away by mass loss during contraction. This will reduce the life-time by a factor of two<sup>4</sup>.

If the star is rotating non-uniformly, with the central regions rotating faster than the surface layers, this will aid stability. An inward increase in  $\omega$  by a factor of 8 would permit a star of  $10^{10} M_\odot$  to reach the hydrogen-burning phase. Such an inward increase may be possible in a convective star with very large turbulent velocities where each turbulent eddy is conserving its angular momentum. This possibility will be considered elsewhere<sup>5</sup>, as it requires an examination of the convective energy transport in massive objects and is outside the scope of the present article.

It should be noted that the stabilizing effect of rotation is due to the presence of  $2T$  in the virial theorem. Consequently any other form of kinetic energy, such as that in the turbulent convection, could also exert a stabilizing influence.

This investigation arose out of discussions with Prof. W. Fowler at the Second Texas Symposium on Relativistic Astrophysics held at the University of Texas, Austin.

## COOLING OF NEUTRON STARS

By DR SACHIKO TSURUTA

Smithsonian Astrophysical Observatory,  
Cambridge, Massachusetts

AND

PROF. A. G. W. CAMERON

Institute for Space Studies, Goddard Space  
Flight Center, New York

THE discovery of discrete sources of X-rays in the sky has led to much speculation as to the mechanisms responsible for the X-ray emission<sup>1-4</sup>. Among these suggestions has been the thermal emission of X-rays from the hot surfaces of neutron star remnants of supernova explosions<sup>1-3</sup>. Calculations of the cooling of such a neutron star following its formation have seemed to indicate that

the temperature would still be several million degrees at an age of several thousand years. Such cooling calculations have been based on estimates of photon emission from the surface and of neutrino-antineutrino pair emission by the plasma process from the interior. There have recently been new suggestions regarding other possible mechanisms of neutrino emission from the interior<sup>5</sup>, and this has led

to the impression that neutron stars might cool too rapidly to be observable as celestial X-ray objects<sup>4</sup>. We believe this view to be too pessimistic, and we give here a brief summary of some of our cooling calculations for neutron stars.

The neutron star models we have used in our calculations have been based on composite equations of state with nuclear forces included. The details of the construction of the equations of state have been described in a thesis<sup>5</sup>, and will be published in due course. At the lowest densities, but still at substantially high temperatures, the composition was assumed to be iron. As the density increases, the main contribution to the pressure comes from the degenerate electrons, and the mean molecular weight per electron gradually increases as the high Fermi level of the electrons forces the nuclear composition of the material to change toward higher mass number. At densities between  $10^{11}$  and  $10^{14}$  g/cm<sup>3</sup> the heavy nuclei gradually dissolve into neutrons. The system then consists of degenerate neutrons, protons and electrons. Near and above  $10^{13}$  g/cm<sup>3</sup>, many other particles appear in the mixture, commencing with the  $\mu$  meson and the  $\Sigma$ -hyperon. In constructing our equations of state, the degeneracy pressures of all the individual fermions were added, and nuclear force terms were also included.

Nuclear forces are generally attractive at large internucleon distances and repulsive at small internucleon distances. In this work we chose forms of the potential interactions between neutrons suggested by Levinger and Simmons<sup>6</sup>. Their potentials  $V_\beta$  and  $V_\gamma$  were utilized. Both these potentials are attractive at low densities, although  $V_\gamma$  is somewhat more attractive than  $V_\beta$ . At high densities  $V_\gamma$  rapidly turns repulsive, while  $V_\beta$  only slowly turns repulsive. For our neutron star equations of state, we have applied these potentials between the baryons without distinction as to the type of baryon. At densities less than, or equal to, nuclear densities, the character of nuclear forces is reasonably well known, and is given to a rough approximation by either of these potentials; and the composition of the matter is mostly neutrons, for which the potentials were originally constructed. At much greater than ordinary nuclear densities many different types of baryon are present, and the

rapidity with which nuclear forces turn repulsive is very speculative. Hence the two potentials  $V_\beta$  and  $V_\gamma$  tend to span a range of possible behaviour of the nuclear forces at high densities, and the differences in the neutron star models which result from the adoption of one or the other potential will give an indication of the uncertainty due to lack of knowledge in this area of physics.

In the case of a perfect fluid there is a general relativistic limitation on the pressure such that it cannot exceed one-third of the proper energy density<sup>7</sup>. In a fluid with suitable anisotropic properties, this condition may be violated; but the ultimate relativistic condition still remains that the pressure cannot exceed the proper energy density<sup>11</sup>. If this were to be violated the speed of sound would exceed the speed of light in the medium. Accordingly, the composite equation of state constructed as already described was cut off with one of these two pressure saturation conditions.

The general relativistic equations of hydrostatic equilibrium were derived by Oppenheimer and Volkoff<sup>11</sup>. For a given assumption about central density, the numerical integration of the differential equations of hydrostatic equilibrium gives models with uniquely determined masses. The gravitational and proper masses determined in this way as a function of central density for the two composite equations of state are shown in Fig. 1. Several interesting comments follow from this figure. It is evident that the details of the structure of the neutron star models are very sensitive to the uncertainties in the rates at which nuclear repulsive forces enter in the baryon mixture at high densities. For each equation of state the mass rises with increasing central density toward a principal peak, beyond which it falls and then oscillates. It is interesting to note that the gravitational mass is less than the proper mass over the entire range of neutron star models, thus showing that such models are gravitationally bound. This is contrary to the behaviour of models constructed with non-interacting neutron gases. A more detailed discussion of the stability of the models beyond the main peak will be given separately<sup>12,13</sup>. It may also be noted that pressure saturation does not set in until the vicinity of the principal peak has been reached. Hence uncertainties in the pressure saturation effects play no significant part in the discussion which follows.

In order to calculate representative cooling curves for neutron star models, three models were chosen so that one was of low mass at the low-density base of the principal peak, one was half-way up the peak, and the other was near the top of the peak. To these models were fitted hot atmospheres corresponding to a series of surface temperatures. These atmospheres were composed of both iron and magnesium; the results were nearly the same, and only the neutron stars with iron envelopes are discussed here. It was typically found that the temperature rose by about a factor of 50 between the photosphere of the neutron star and the interior where the high thermal conductivity of the electrons assured a flat temperature distribution. The atmospheres were constructed with the help of opacities calculated from the Los Alamos opacity code of A. N. Cox *et al.* The atmospheric structure was determined by requiring that the luminosity should not change from one layer to the next.

The heat capacity of the neutron star models is a function of their temperature<sup>14</sup>. The presence of nuclear forces in the equation of state will modify the heat capacity by an amount which typically can be of the order of a factor 2, according to rough estimates which we have made. We did not take such modifications into account in making the actual cooling calculations.

The cooling of the neutron stars is due to the combination of neutrino emission from the interior and photon emission from the surface. The construction of the envelope automatically provided us with the photon cooling rates. Three neutrino cooling rates were taken into account, as follows:

Fig. 1. Gravitational (—) and proper (---) masses of the neutron star models constructed with both composite equations of state and plotted as a function of central density. The different models resulting from the two pressure saturation conditions at the highest densities are separately indicated.

(1) *Neutrino pair emission from the plasma process.* These neutrinos arise from the decay of plasmons in the degenerate electron gas in the interior of the neutron star. The rates have been given by Adams, Ruderman and Woo<sup>18</sup> and by Inman and Ruderman<sup>19</sup>.

(2) *The URCA process.* Bahcall and Wolf have recently given an estimate of neutrino emission from this process<sup>7</sup> in which neutrons decay into protons and protons capture electrons. The rate is somewhat greater than that of the plasma process.

(3) *The neutrino bremsstrahlung process.* The neutrino pairs are emitted when electrons scatter from positive or negative baryons in the interior of the neutron star. M. A. Ruderman and G. Festa (private communication) have kindly provided us with the following approximate preliminary expression for this process:

$$q \left( \frac{\text{ergs}}{\text{g-sec}} \right) = 10^8 Z^2 \frac{n_s}{n} (T_s)^4$$

for  $E_F \gg mc^2$

where  $Z$  is the effective charge of the electron scattering centres,  $n_s$  is the number density of such centres, and  $n$  we take here to be the baryon number density. Ruderman and Festa have suggested that there may be proton clustering in neutron star interiors in the presence of very large numbers of neutrons, so that the effective charge of scattering centre might be 2. However, it may well be that under conditions of interest in the interiors of neutron stars there will also be a large number of  $\Sigma^-$  hyperons, which may hinder the clustering process. Consequently, we have chosen to take the effective charge of a scattering centre equal to unity and to count as the scattering centres both the protons and the  $\Sigma^-$  hyperons. This process is less important than the URCA process at high temperatures, but it is more important at low temperatures.

The cooling curves for the six chosen neutron star models as a function of age are shown in Fig. 2. It may be seen that the rate of cooling has a significant dependence on the mass of the star. The low-mass stars cool quite rapidly, but the medium and heavy mass stars still have temperatures exceeding  $2 \times 10^8$  °K for times of the order of  $10^4$  or  $10^5$  years. Hence it is evident that thermal emission of X-rays from neutron star surfaces should continue to be regarded as candidates for identification with some of the X-ray sources which are being found in the sky.

Bahcall and Wolf<sup>7</sup> have raised the question of neutrino cooling from pion decays in neutron star interiors. Such pion decays can occur only if pions should have a small effective mass in the presence of a largely neutron gas. Both Bahcall and Ruderman have indicated to us (private communications) their expectations that, under the conditions in which pions may be present in a neutron star, there will be a predominantly repulsive interaction between the pions and the neutrons. This would raise, rather than lower, the effective mass of the pions, and make it very unlikely that pions will be present in the interiors of neutron stars on the low-density side of the principal peak.

Fig. 2. The cooling curves for selected neutron star models fitted with atmospheres of iron, with three models for each composite equation of state. In the portions of the curves to the left of the crosses cooling occurs predominantly by neutrino emission from the interior; to the right of the crosses photon cooling from the surface predominates. —,  $V_p$ ; ---,  $V_n$ ; x, cooling rates equal.

The remarkable NRL rocket experiment carried out during a lunar occultation of the Crab Nebula has shown that the X-ray source associated with the Crab Nebula has dimensions very much larger than those of a neutron star. One of us has suggested that these X-rays may be due to the synchrotron process from high energy electrons accelerated in the magnetosphere of a vibrating neutron star<sup>4</sup>. Similar non-thermal processes may well be associated with other X-ray sources, if they are neutron stars, and hence non-thermal components to X-ray spectra may be common. Hence we believe that many more highly refined experiments will be necessary before the true nature of the celestial X-ray sources will be determined.

We thank Dr. M. A. Ruderman and Mr. G. Festa for communicating to us in advance of publication their preliminary results on neutrino emission by the bremsstrahlung process.

## INTERSTELLAR EXTINCTION BY GRAPHITE GRAINS

By DR. N. C. WICKRAMASINGHE

Jesus College, Cambridge

AND

Miss C. GUILLAUME

Institut d'Astrophysique, Liège, Belgium

MANY observational data have recently accumulated on the law of interstellar extinction in the galaxy<sup>1-3</sup>. The general trend of the new results appears to be a considerable variability in the extinction law. The 'unique extinction law' hitherto believed to be generally valid now appears to hold only in limited regions of the sky. The results of a recent investigation by Johnson<sup>4</sup> indicate different extinction curves for Cygnus, Orion,

Perseus, Cepheus and NGC 2244 (Fig. 1). Dr. K. Nandy<sup>18</sup> also obtains different extinction curves for Cygnus and Perseus. The observations of Johnson<sup>4</sup> are normalized to give an extinction of 1 mag. at  $\lambda = 5470$  Å.

From a theoretical point of view the present situation is in fact quite satisfactory. To understand a unique extinction law one has to impose very stringent conditions on the sizes of interstellar particles. For a physically

Fig. 1. Regional extinction curves plotted from data of Johnson (ref. 2). 1, Perseus; 2, Orion Belt; 3, NGC 2244; 4, Cygnus; 5, Cepheus

realistic size distribution of ice grains<sup>4</sup> the mean particle radius has to be specified to within a few per cent in order to fit the reddening curve for Cygnus. The physical accident required to produce this precise mean size in every part of the galaxy is very difficult to understand, and is perhaps the most unsatisfactory feature of the traditional explanations.

With graphite grains the situation appeared to be somewhat better. For the original model proposed by Hoyle and Wickramasinghe<sup>5</sup>, the 'unique reddening law' then accepted appeared to arise quite naturally from the extinction formula for very small particles. The reddening law was thus determined essentially by the assumed refractive index of graphite, provided the grains were all sufficiently small.

The data on the refractive index of graphite available at the time of the Hoyle-Wickramasinghe paper were, however, very sparse. A constant conductivity  $\sigma = 1.2 \times 10^{11} \text{ sec}^{-1}$ , and a dielectric constant  $K = 2$ , was assumed on the basis of old reflectivity measurements limited to a few optical wave-lengths. The refractive index  $m$  of graphite was therefore taken to be given by:

$$m^2 = K - 2i\sigma\lambda/c \approx 2 - 8i\lambda \quad (1)$$

with  $\lambda$  in microns, over the whole of the relevant wave-length range.

In a recent paper, Ergun and McCartney<sup>6</sup> reported measurements of the absorptive index at wave-lengths between 2100 Å and 5500 Å, of single graphite crystals. Their observations, which indicated a sharp peak near 2600 Å, appear to be inconsistent with the earlier assumption of a constant conductivity<sup>7</sup>. More recently Carter, Huebner, Hamm and Birkhoff<sup>8</sup> and Taft and Philipp<sup>9</sup> have reported direct measurements of the real and imaginary parts of  $m^2$  from 1100 Å in the ultra-violet into the far infra-red. The results of Taft and Philipp<sup>9</sup> are in general accord with the Ergun-McCartney results for the region of overlap of their investigations.

Let us denote the real and imaginary parts of  $m^2$  by  $\epsilon_1$ ,  $\epsilon_2$ , respectively. For our present investigation we shall

Table 1. OPTICAL DATA FOR GRAPHITE

$\lambda^{-1} (\mu^{-1})$	$\epsilon_1$	$\epsilon_2$	$n$	$k$
0.47	4	21.3	2.583	2.973
0.86	4	11.6	2.582	2.034
1.19	4	8.4	2.579	1.650
1.56	4	7	2.456	1.425
1.73	4	7	2.456	1.425
1.83	4	7	2.456	1.425
1.93	4	7	2.456	1.425
2.26	4	7	2.456	1.425
2.30	4	7	2.456	1.425
2.49	4	7	2.456	1.425
2.68	4	7	2.456	1.425
2.78	3.8	7	2.425	1.443
3.01	2.3	7.5	2.253	1.665
3.85	-3.4	7	1.480	2.865
4.54	-2	2.8	0.840	1.649
5.00	-1	2	0.786	1.273
6.67	1.2	0.6	1.127	0.256

adopt the values of  $\epsilon_1$ ,  $\epsilon_2$  extracted from the graphs of Taft and Philipp (TP<sup>9</sup>) and Carter, Huebner, Hamm and Birkhoff (CHHB<sup>8</sup>). Fig. 3 of CHHB gives  $\epsilon_1$ ,  $\epsilon_2$  as functions of wave-lengths in the range  $1100 \text{ Å} < \lambda < 3000 \text{ Å}$ . For  $\lambda > 3000 \text{ Å}$   $\epsilon_1$  remains approximately constant until the far infra-red;  $\epsilon_2$  remains approximately constant until  $\lambda \approx 7000 \text{ Å}$  and thereafter begins to rise steeply (TP, Fig. 2). For  $\lambda > 7000$  the case of a constant conductivity is realized (TP, Fig. 6) so that  $\epsilon_1 = -2\sigma\lambda/c$ , increases as  $\lambda$ . The values of  $\epsilon_1$ ,  $\epsilon_2$ ,  $n$  and  $k$  emerge as given in Table 1. These data probably represent the best available at the present moment and apply for light polarized with electric vector parallel to the basal planes.

Using these values of  $m = n - ik$ , the efficiency factors for extinction of light by spherical graphite grains may be calculated from the Mie formulae. A detailed account of these computations will be published elsewhere; only a summary of the more important features of our results will be given here.

For grains of a single radius  $a$  in the line of sight of a star, the resulting extinction in magnitudes is related to the efficiency factor  $Q_{\text{ext}}$  for a single grain by:

$$\Delta m(\lambda) = 1.086 N \pi a^2 Q_{\text{ext}}(\lambda) \quad (2)$$

where  $N$  is the number of grains in the line of sight. For comparison with observations a normalized extinction  $E(\lambda)$  is defined by:

$$E(\lambda) = \frac{Q_{\text{ext}}(\lambda)}{Q_{\text{ext}}(\lambda_0)} \quad (3)$$

where  $\lambda_0 = 5470 \text{ Å}$ . The normalization adopted is the same as that of Johnson<sup>2</sup> and is such that  $E(\lambda) = 1 \text{ mag}$  at  $\lambda = \lambda_0$  (Fig. 1).

Fig. 2

Fig. 3

The theoretical curves of  $E(\lambda)$  for various graphite grain radii are plotted in Figs. 2 and 3. The open circles plotted in Figs. 2 and 3 represent the extinction curve given by Boggess and Borgman<sup>1</sup> including their ultra-violet observations.

It is seen that the shapes of the theoretical curves for  $\lambda^{-1} < 3$  (Figs. 2 and 3) bear a general resemblance to the observational curves in Fig. 1. There seems to be little doubt that any of the observational curves reported by Johnson, with the possible exception of Cepheus and NGC 2244, cannot be reproduced by a suitable mixture of graphite grain sizes. The curves for Cepheus and

NGC 2244 have been plotted from observations of 5 and 3 stars respectively. Data for more stars are required before we can accept the curves reported for these two regions.

The most distinctive feature of graphite absorption, however, occurs in the ultra-violet. Very small graphite particles are able to produce a sharp quenching effect in the ultra-violet near 2200 Å (Fig. 2). For a grain of radius 0.016 μ,  $Q_{\text{ext}}(2200)/Q_{\text{ext}}(5470) \approx 12.3$ ; the extinction thereafter decreases until at 1500 Å,  $Q_{\text{ext}}(1500)/Q_{\text{ext}}(5470) = 2.41$ . The quenching effect decreases in absolute value for larger sizes, but the maximum at 2200 Å and a minimum at 1500 Å remains (Fig. 3). There is a strong possibility that this is in fact the effect observed by Boggess and Borgman<sup>1</sup>. On the basis of graphite absorption one would also expect a fairly sharp drop in the extinction curve towards 1500 Å. This is in fact the remarkable outcome of a preliminary investigation by Dr. J. Borgman<sup>10</sup>. Such a result, if confirmed, would give strong support to the graphite grain theory. On the basis of pure ice grains it does not seem possible to explain the ultra-violet measurements<sup>4</sup>.

Moreover, recent attempts to isolate certain infra-red interstellar absorption bands to be expected on the basis of ice or dielectric absorption have produced negative results<sup>11</sup>. Although the accuracy of the rocket experiments might be questioned, the absence of these bands if further established would provide additional evidence against ice absorption.

## GENETIC INVESTIGATIONS OF AUTOIMMUNE DISEASE IN MICE

By SIR MACFARLANE BURNET, O.M., F.R.S., and MARGARET C. HOLMES

The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

FOR several years we have had under intensive study the unique mouse strain [NZB/BL], developed by Bielschowsky *et al.*<sup>1</sup>. These mice develop an autoimmune type haemolytic anaemia which, in almost all respects, presents close analogies to the human disease, acquired haemolytic anaemia and, in particular, to the 'warm' antibody type of Dacie. Investigations of the natural history of these mice and of the haematological characters of their disease have been published both from the Otago laboratory in which they were developed<sup>2,3</sup> and from Melbourne<sup>4,5</sup>. One paper on the behaviour of the F1 cross NZB × O3H has been published<sup>6</sup> and a good deal on the NZB × NZW F1 hybrid which has a strikingly high incidence of kidney disease<sup>7,8</sup>.

With the partial completion of studies on NZB × O3H and NZB × AKR F1 and back-crosses and less complete results from NZB × NZW, NZB × O37 BL and NZB × T6 F1's, a considerable amount of material has now been obtained. In this article we wish to discuss the behaviour of the Coomb test as an index of the autoimmune processes in the various F1 hybrids and back-cross populations.

The test involves the detection of incomplete antibody on the surface of the animal's red cells. Technical details

are described elsewhere<sup>9</sup> but, in outline, mice are bled from the tail at monthly intervals, the red cells washed four times in warm saline and then tested for slide agglutination with two dilutions 1:5 and 1:50 of a standard antiserum. The test sera were prepared in rabbits immunized with mouse globulin (almost wholly Ig G) and absorbed before use with normal mouse red cells. In this way, large numbers of results roughly quantitative in character, since the intensity ± to +++ of agglutination for two dilutions was noted, became available. From the raw data arranged according to nominal months (28 days) each mouse was allotted a time, for example, 11.5 'months' as representing the first time it was definitely positive. As it was not always possible to test all mice every 4 weeks, when necessary a value was interpolated. Normally, if the first positive reaction from a mouse showed +++ agglutination with both dilutions of serum and the mouse had not been tested during the previous two months, its conversion was pre-dated one month.

The proportion positive at any month was calculated in terms of the total number of mice previously converted plus those changing during the month plus the number of still negative mice present throughout the period. Once

Fig. 1 Times of first change from Coombs-negative to Coombs-positive (Coombs conversion) for  $F_1$  and back-cross hybrids of strains  $NZB$  and  $AKR$ . Cumulative percentage of conversions obtained as described in the text plotted on probability paper.  $F_1$   $NZB/AKR$  (male,  $\times$ , female,  $\circ$ ;  $BC/NZB$  back-cross ( $F_1$   $NZB \times AKR$ )  $\times$   $NZB$ ;  $BC/AKR$  back-cross ( $F_1$   $NZB \times AKR$ )  $\times$   $AKR$ ).

a mouse had given a definite positive reaction ( $DO+$ ) it was counted as positive throughout the calculations irrespective of whether it had reverted to negative or not. This gave a cumulative percentage which could conveniently be plotted on probit paper.

The strains concerned,  $NZB$ ,  $NZW$ ,  $OSH$ ,  $AKR$  and  $CS7 BL$ , are maintained in the Institute by brother-sister mating.  $T6$  males were obtained by the courtesy of Dr. Peter Ilbery. The standard  $F_1$  crosses were made by mating  $NZB$  females with males of the other parent strain, and, for the back crosses,  $F_1$  females were mated with a male of the appropriate parental strain.

Small numbers of each of the parent strains, other than  $NZB$ , have been shown to be Coombs-negative at  $\pm$  one year of age and, in the absence of reports to the contrary, we have assumed that they are uniformly Coombs-negative throughout life. In the case of  $OSH$  and  $AKR$ , this assumption is almost completely validated by the results with the back-crosses described here.

**$NZB \times AKR$  hybrids.** In the  $NZB-AKR$  series the results (Fig. 1) indicate an approximately normal distribution of the times of conversion, but in the  $F_1$ , and particularly in the females, there is a persistent failure to convert a significant proportion. The median times of conversion supply most of the information but, in addition, there are differences in the slope of the curve (corresponding to the size of the standard deviation) and in the proportion of positive reactions which afterwards become negative. These are not shown in Fig. 1, which is concerned only with the time of the first recognized conversion from a negative to a positive direct Coombs test.  $NZB$  mice show a median age of conversion of 160 days for males, 188 for females\* (see Table 1).

The  $F_1$   $AKR \times NZB$  strain shows a marked difference between male and female, but in the opposite direction from  $NZB$ , the female converting earlier and showing a steeper slope than the male.

Except when lymphoid tumours develop, the great majority of  $NZB$  conversions are permanent, but in all the hybrids we have studied there has been some irregularity in the results of successive Coombs tests, and it may

Table 1. MEDIAN AGE FOR COOMBS CONVERSION IN DAYS

	Male	Female
$NZB$	160	188
$NZB \times OSH$ $F_1$	—	540
$F_1 \times NZB$ $BC$	310 $\pm$	310 $\pm$
$F_1 \times OSH$ $BC$	—	—
$NZB \times AKR$ $F_1$	454	342
$F_1 \times NZB$ $BC$	310	310
$F_1 \times AKR$ $BC$	—	—
$NZB \times CS7$ $F_1$	425	425
$NZB \times T6$ $F_1$	730 $\pm$	510
$NZB \times NZW$ $F_1$	—	320

Table 2. IRRREGULARITIES IN COOMBS RESPONSE IN  $NZB \times AKR$   $F_1$  MICE

Type of response	Male	Female
A Positive persisting in all later tests	6 25%	14 54%
B Early irregularities with final stable positive	4 17%	0
C Various irregularities not ending as positive	6 25%	6 23%
D Definite positive for at least 2 months, afterwards negative	5 21%	3 11%
E Always negative	3 12%	3 11%
Total tested	24	26

Table 3. DISTRIBUTION OF COOMBS'S RESPONSES IN RELATION TO THE PRESENCE OF LYMPHOID TUMOURS AND TO PROLONGED SURVIVAL

Type of response	Lymphoid tumour		Survived 800 days	Overall	
	M	F		M	F
Standard $AB$	0	2	0	10	14
Irregular $CD$	3	6	4	11	9
Negative $E$	0	1	3	3	3

be desirable to give some detail of the results with the  $NZB \times AKR$   $F_1$  hybrids. Table 2 shows a division into the several types of response that followed the first appearance of a positive Coombs reaction. Although the proportion giving at least one positive is essentially the same (88–90 per cent) for both sexes, females not only show earlier change but are less prone to show irregular responses, 54 per cent as against 25 per cent in males showing persisting positive reactions once Coombs conversion had occurred.

Of the 50 mice studied in detail and recorded in Table 2, 3 males and 9 females died with unequivocal lymphoid tumours while 7 males and no females survived more than 800 days (Table 3).

It is clear that, as might be expected, the development of a lymphoid tumour was significantly associated with irregularity of the Coombs reaction. It is perhaps no more than an interesting lead that no mouse that developed a persisting Coombs test survived 800 days while the only 3 male mice which were consistently negative from 14 months onward all survived more than 800 days.

The back-cross to  $AKR$  produced a considerable number of cases of lymphoma/leukaemia which will be described elsewhere, and the very low incidence of Coombs conver-

Fig. 2. Times of Coombs conversion for  $NZB$ ,  $OSH$   $F_1$  hybrids and back-crosses.

Legend as Fig. 1.  $BC/NZB$  back-cross ( $F_1$   $NZB \times CSH$ )  $\times$   $NZB$ ;  $BC/OSH$  back-cross ( $F_1$   $NZB \times CSH$ )  $\times$   $OSH$ .

sion may be related in part to early death from leukaemia. However, when tested at 350–400 days, 1/45 males and 1/56 females were  $DC+$ , both reactions persisting, while of tests made between 450 and 550 days when many had died of leukaemia, 2/24 males and 2/19 females were positive. It is not legitimate to give a definite figure for the percentage of Coombs converters, but it is unlikely to exceed about 10–15 per cent.

It is clear from Fig. 1 that in both back-crosses the Coombs behaviour shows no resemblance to what would be obtained from a population of equal numbers of  $F_1$  and parent. The difference between the capacity to allow a positive  $DC+$  test at any time during the life of the mouse and its absence cannot therefore be produced by a single gene change.

**NZB-C3H crosses.** The results of  $F_1$  and of the back-cross to NZB have already been published\*. Fig. 2 is drawn from the same data used in that paper with additional results from 50 mice back-crossed to C3H. It will be seen that there is a greater difference between male and female for the  $F_1$  results than is shown in the NZB  $\times$  AKR series. The back-cross to NZB showed conversion to  $DC+$  at an intermediate period between NZB and  $F_1$ . The number of mice involved was small (male 26, female 23) and, in view of the considerable scatter of the male values, it is not possible to say that there is a significant male-female difference. In the back-cross  $F_1(NZB \times C3H) \times C3H$  there were only two typical  $DC+$  tests, both in old males. Two females out of 25 tested at about one year of age gave a weak positive (but well controlled and definite) test which afterwards became negative. Twelve females surviving two years were all negative.

**Other NZB crosses.** Three other strains have been used in crosses with NZB, namely, NZW C57BL and T6, and in each case about 50 mice were studied by serial Coombs tests. The  $F_1$  results for NZB  $\times$  C57BL and NZB  $\times$  T6 are shown in Fig. 3. The first series differs from the others in showing no significant differences between males and females. The NZB  $\times$  T6  $F_1$  mice show the usual greater activity of females reaching 50 per cent conversion in about 500 days, while there were still 10 males alive beyond 750 days which had never given a positive test.

The chief interest of the NZB  $\times$  NZW cross is the very high mortality from kidney disease and this has the effect of eliminating all females before 400 days and greatly

Fig. 3. Times of Coombs conversion for NZB  $\times$  C57BL and NZB  $\times$  T6  $F_1$  hybrids. Legend as Fig. 1

Fig. 4. Times of Coombs conversion for NZB  $\times$  NZW  $F_1$  hybrids. Legend as Fig. 1. Note that, owing to early deaths from kidney disease, the figures for both sexes are based on small numbers.

depleting the numbers of males available for Coombs test at later stages\*. However, the trend was clearly similar to the other crosses and most of the surviving females more than 300 days of age were positive, while there were only two males for whom a late  $DC+$  was recorded (Fig. 4).

### Discussion

For several years we have regarded the 'forbidden clone hypothesis' as the most satisfactory way of co-ordinating the facts of autoimmune disease. The availability of the present results from genetic experiments offers new material for an attempt to disprove or modify the hypothesis. In broad terms, the forbidden clone hypothesis of autoimmune disease is an almost necessary corollary of a clonal selection approach to immunity. It assumes that abnormal auto-antibodies or pathogenic immunocytes are the product of clones which have been allowed to develop by the failure of some homeostatic process to prevent the emergence of lymphoid (immunocyte) stem cells with immune patterns that can react with antigenic determinants present in accessible body components. Formally, the homeostatic process in question might fail either because the process itself was ineffective or because a stem cell resisting the process had appeared by somatic mutation. From such a cell a descendant forbidden clone of immunocytes could arise with pathogenic potentialities. It must be emphasized that the mutation producing a forbidden clone is not in virtue of the appearance of an immune pattern which reacts with a body component via one of its antigenic determinants, but because of its resistance to a homeostatic process, possibly active in the thymus, which should normally destroy all cells with such patterns as they arise.

In the homozygous NZB mice the appearance of a positive direct Coombs test is a convenient indicator that a population of pathogenic cells has developed to a demonstrable level. Appropriate transfer experiments<sup>10,11</sup> have shown that a cell population of adequate size is present only in the spleen of mice already Coombs-positive. Transfer to young isologous mice will regularly produce

a temporary  $DO+$  reaction (sometimes persisting) and, in addition, enlargement of spleen possibly analogous to Simonsen's graft-versus-host reaction<sup>14</sup>. These reactions are absent in young recipient mice given control material and in mice that will not accept  $NZB$  cells, that is, all except isologous animals or  $F1$  mice with one parent  $NZB$ .

If such cells arise by somatic mutation, the regularity of their appearance needs to be accounted for. For one cell to have  $10^5$  descendants, which seems likely to be the order of the number of cells giving antibody capable of coating all the red cells of the body, 20 binary generations are needed. Having regard to the unlikelihood of proliferation at maximal speed of such a clone, we can probably allow 20 days from the emergence of the mutant stem cell to the appearance of a  $DO+$  reaction. The time of emergence of such a mutant cell would then be, for male  $NZB$ , 80–220 days, and for females, 108–248 days, based on a median time for appearance of the  $DO+$  reaction of male 160 days, female 188 days. The general resemblance of this time-scale with that for the emergence of leukaemia in strain  $AKR$  mice<sup>15</sup> suggests that, if somatic mutation is the rate determining process in  $AKR$  leukaemia, it is equally likely to be so for  $NZB$  haemolytic anaemia.

Our approach to an interpretation of the data that have been presented will be to assume, following Burch<sup>14</sup>, that both an appropriate genotype and a process of somatic mutation are necessary for the manifestation of haemolytic anaemia in  $NZB$  mice. In the absence of compelling reasons to the contrary it is simplest to assume that the initiating somatic mutation allows a cell to escape the normal homeostatic process by which immunocytes capable of reacting with accessible body components are destroyed or inhibited, and that this change  $R^+$  to  $R$  may occur in any breed of mice. The emergence of descendants of such a cell in sufficient numbers to produce the phenotypic expression of Coombs conversion will obviously be influenced by many factors. A further somatic mutation or sequence of mutations may be needed and, on Burch's view, would probably be the dominant rate-controlling process. The results we have reported here, however, suggest strongly that phenotypic expression of the (final) somatic mutation both as regards timing and intensity depends on the nature of a gene complex  $B$  which is present in a specially favourable form in male  $NZB$  mice.

The complexity of  $B$  is evidenced by the results of back-crosses shown in Figs. 1 and 2. Back-crosses to the 'normal' parental strain gave less than 10 per cent showing Coombs conversion but in each set there were one or two strongly positive reactors. If we take the simplest possible assumption, this would indicate that 3–5 unlinked genes were included in the complex. Similarly, in the back-crosses to  $NZB$ , the timing of the change to  $DO+$  is

intermediate in character between  $NZB$  and  $F1$  but is not interpretable as a mixture of the two types. In the reconstruction of the  $B$  complex in the various  $F1$ 's and back-crosses there will be possibilities of influence on time of conversion as well as of determining whether conversion can or cannot occur. The influence of sex is clear in nearly all the populations studied and obviously some of the components of the gene complex  $B$  are carried on the  $X$  chromosome. We hope to look for more direct evidence of this by appropriate reciprocal matings. Results, however, may be difficult to interpret since we have shown that in homozygous  $NZB$  mice the earlier and more active change to  $DO+$  is in males, while in most  $F1$ 's the females carrying one  $X$  chromosome derived from  $NZB$  and one foreign  $X$  convert earlier than the males with only the  $NZB X$  in their genome.

The findings are in general accord with the hypothesis of a specific type of somatic mutation the results of which depend on the rest of the genetic environment. They would be equally in accord, however, with an appropriately developed hypothesis that the somatic genome was actively modified by the incorporation of part of a virus genome giving a heritable somatic genetic change. So far there is no evidence from any other direction for the presence of a virus, but, if it is postulated that the virus is transmitted vertically by sperm as well as ovum and can demonstrably affect only animals of a strictly limited range of genotypes, it becomes very difficult to disprove the virus hypothesis experimentally.

In the course of these experiments a large amount of data on mortality with special reference to leukaemia-lymphoma and lethal kidney disease was accumulated. The incidence and type of proliferative lesions in the thymus have also been recorded. These findings and their relationship to the distribution and age incidence of Coombs conversion will be discussed elsewhere.

This work was supported by grant AI-05767 from the National Institute for Allergy and Infectious Diseases, U.S. Public Health Service. We thank Miss J. Watson for carrying out most of the Coombs tests.

## EXAMINATION OF THE MECHANISM OF ANTIBODY FORMATION USING NUCLEIC ACID AND PROTEIN INHIBITORS

By PROF. R. S. SPEIRS

Downstate Medical Center, State University of New York, Brooklyn 3, New York

RECENT experiments have demonstrated that antibody production can be considered as a form of protein synthesis which is regulated by nucleic acids and follows metabolic pathways similar to those utilized for other types of protein. It is formed on ribosomes<sup>1</sup> from a pool of free amino-acids<sup>2,3</sup> according to mRNA which is coded from chromosomal DNA<sup>4,5</sup>. However, high antibody titres have been obtained during the anamnestic response to antigen in the presence of nucleic acid inhibitors<sup>6</sup>. These observations suggest that RNA

necessary for antibody synthesis must be capable of being stored, and that this accumulated RNA can be rapidly activated even in the presence of DNA inhibitors. It would appear that the primary exposure to antigen results in an inactivation of RNA coded for antibody synthesis, while a later re-exposure to specific antigen produces a reactivation of the RNA and a rapid synthesis of antibody<sup>7-9</sup>.

In view of these considerations, attempts were made to modify the degree of immunization by altering the

quantity of nucleic acids present in the cells at the time of primary exposure to antigen. Three experimental approaches were used: (a) cells were treated with nucleic acid and protein inhibitors at the time of primary exposure to antigen, and antibody production was measured during the anamnestic response; (b) the inhibitors were added to antigen to determine whether repeated injections would result in a prolonged suppression of immunity; (c) the inhibitors were added to antigen and then injected into immunized animals to ascertain whether a decrease in antibody response would occur.

The effect of antibiotics on the immune response was determined in adult *BDF<sub>1</sub>* mice.

In the first experiment, each of 60 mice was given 2 injections of Freund's adjuvant plus tuberculin (Difco), spaced 10 days apart, in order to produce a localized population of peritoneal inflammatory cells. Four days after the second injection of adjuvant, the animals were given a primary injection of fluid tetanus toxoid (Lederle). Antibiotics were administered intraperitoneally at 12-h intervals for a total of 5 days beginning 12 h prior to the primary antigen injection. In group A, the mice were re-injected with the water-soluble or fluid tetanus toxoid at bi-weekly intervals. In group B, the mice were injected with a precipitated antigen consisting of tetanus toxoid adsorbed on aluminium phosphate (Lederle).

In the second experiment, the antibiotics were combined with fluid tetanus toxoid and administered to 40 mice. A total of 8 weekly intraperitoneal injections of 0.4 ml. each were given. The animals were then allowed to recover for a 3-week period before being given further injections of tetanus toxoid.

In the third experiment, 40 mice were first immunized by 2 intraperitoneal injections of tetanus toxoid incorporated into Freund's adjuvant. They were then given 5 weekly intraperitoneal injections of tetanus toxoid combined with the antibiotics.

The inhibitors used were actinomycin D (Merck, Sharpe and Dohme), chloramphenicol (Parke Davis), methotrexate (Lederle), streptomycin, and puromycin (Nutritional Biochemical). These inhibitors were suspended in pyrogen-free saline and injected into groups of 5 animals as indicated in Tables 1-3.

All mice were bled at weekly intervals and the antitoxin titres determined. 0.1 ml. of blood was removed from the tail vein and immediately diluted with 2 ml. distilled water to lyse the cells. Blood from a pool of 5 animals was serially diluted against equal parts of a standardized tetanus toxin solution. The antitoxin titres were determined by biological assay. Duplicate assays were run after the diluted blood had been frozen and stored for 4 or more weeks. In this manner all the sera from a particular experiment could be re-assayed together and the titres compared under nearly identical conditions. Once antitoxin production was initiated, the titres increased progressively following each succeeding injection of antigen. Therefore, in order to simplify the presentation of the data, only bi-weekly titres are included in Tables 1-3.

The degree of primary immunization obtained after a single injection of a water-soluble antigen was too low to be measured by the assay procedure used. However, following each re-injection of the toxoid, progressive increases in titres were obtained (Table 1A). After the fourth injection, the control animals and the animals injected with puromycin, chloramphenicol, erythromycin, and streptomycin had antitoxin titres varying between 45,000 and 90,000 units/ml. blood. Animals receiving 250 µg methotrexate had antitoxin titres of 10,800 units, and animals injected with 10 µg actinomycin D had titres of only 2,400 units. All animals challenged with aluminium phosphate adsorbed tetanus toxoid (Table 1B) had consistently higher titres than animals challenged with fluid tetanus toxoid. The animals previously treated with methotrexate or actinomycin D had markedly

Table 1. EFFECT OF INHIBITORS ADMINISTERED DURING PRIMARY INJECTION OF TETANUS TOXOID ON THE ANAMNETIC RESPONSE

Total dose of inhibitors*	Antitoxin titres 7 days after antigen injection			Mice surviving

† Number  $\times 10^4$  equals antitoxin titres/ml. whole blood.

reduced titres, compared with titres of the control animals.

In the second experiment, the nucleic acid inhibitors were added to tetanus toxoid and then injected into mice at weekly intervals for a total of 8 injections. These results are shown in Table 2. It may be seen that during the 8 weeks of injection, the addition of 10-40 µg per week of methotrexate had no significant inhibitory effect on antitoxin titres. On the other hand, weekly doses of 5.0 µg or more of actinomycin D had a marked inhibitory effect on antitoxin titres during the entire 8-week period. When re-injected with the toxoid only, these animals were found to respond by producing antitoxin titres typical of a primary response. The animals treated with methotrexate had consistently higher titres than the controls.

In the third experiment, the nucleic acid inhibitors were added to tetanus toxoid and then injected into highly immunized mice. Table 3 presents the antitoxin titres obtained. It may be seen that all animals showed progressive increases in antitoxin titres in spite of the presence of inhibitors. In the control animals and in animals receiving methotrexate, titres of more than a million units/ml. blood were obtained. Similar results were obtained in animals injected with 2.5 µg of actinomycin D. However, titres of only 180,000 and 360,000

units were obtained in animals injected with 5–20  $\mu$ g actinomycin D.

The data obtained in these experiments indicate that injections of actinomycin D, given at the time of primary injection of antigen, markedly reduce the antitoxin titres obtained during the anamnestic response. Treatment with a total dose of 10  $\mu$ g or 20  $\mu$ g actinomycin D resulted in markedly reduced antitoxin titres when the animals were later subjected to repeated challenging injections of either fluid tetanus toxoid or the aluminium-adsorbed toxoid. Moreover, when 10 or 20  $\mu$ g actinomycin D was combined with antigen and then injected weekly for a period of 8 weeks, no measurable antitoxin titres were obtained, compared with 45,000 units in the control animals (Table 2). When allowed to recover from the actinomycin D poisoning they were found to be capable of becoming immunized. Although actinomycin D did not prevent antibody synthesis in immunized animals, it did produce a reduction of titres when repeatedly injected along with the antigen (Table 3).

These results differed somewhat from results reported by Wust *et al.*<sup>8</sup>, who observed that actinomycin D injections in rats delayed the production of antibody to heterologous red blood cells, but did not inhibit the total amount of antibody produced. In our experiments, the 10  $\mu$ g actinomycin D produced a temporary inhibition of immunity, but the mice were capable of responding to later injections of the fluid toxoid (Table 1). Furthermore, the mice which had complete inhibition of antitoxin, produced by 8 weekly injections of toxoid plus actinomycin D, later showed a primary response to the toxoid when injected without the inhibitor (Table 2). It would therefore appear probable that in the experiments of Wust *et al.* the injected red blood cells remained in the rats and acted as a continuing stimulus after the inhibitory effects of actinomycin D had worn off.

Actinomycin D is a polypeptide antibiotic which blocks the synthesis of RNA by combining specifically with the guanine base of the DNA molecule, without markedly inhibiting DNA synthesis<sup>10</sup>. It would appear that a reduction in RNA synthesis at the time of primary antigen injection diminishes the capacity of the cells to become sensitized to the antigen, since rapid high antitoxin titres, indicative of 'immunological memory', did not occur following a re-injection of antigen. Repeated simultaneous injections of antibiotic and antigen resulted in prolonged immunological unresponsiveness.

Methotrexate is a folic acid antagonist which binds to folic acid reductase, eventually inhibiting nucleic acid synthesis. Its action appears to be primarily on DNA, resulting in irregular chromatin masses, and an inhibition of DNA synthesis<sup>11</sup>. Injections of methotrexate reduced the amount of primary immunization (Table 1), but appeared to have no inhibitory effect on antibody production when repeatedly injected with the antigen (Tables 2 and 3).

In the doses administered puromycin, streptomycin, erythromycin and chloramphenicol had no marked inhibitory effect on primary immunization (Table 1). Since these substances inhibit protein synthesis without preventing the synthesis of RNA<sup>12–15</sup>, it would appear that a blockage of protein synthesis *per se* does not prevent immunization to a primary injection of antigen. This is further substantiated by experiments of Weisberger *et al.*<sup>12</sup>, who demonstrated that doses of chloramphenicol which completely blocked measurable protein synthesis during the primary response did not inhibit the anamnestic response to a later re-exposure.

In the experiments reported, there was a marked loss of weight and a high death rate in animals receiving doses of nucleic acid inhibitors sufficiently high to block antitoxin synthesis to a primary injection of antigen. Since the reduction in the anamnestic response produced by actinomycin D was still apparent long after the toxic effects of the antibiotic had worn off (Table 1), it was

evident that failure of primary immunization rather than temporary inhibition of response must have occurred. Failure to induce an 'immunological memory' does not appear to be due to an inhibition of protein synthesis, since protein inhibitors *per se* do not produce this effect. However, the lack of primary immunization may be due to a reduction in the available RNA involved in protein synthesis. Since actinomycin D poisoning inhibits RNA synthesis, there would be a gradual reduction in messenger, ribosomal and transfer RNA within the cells<sup>4</sup>. The evidence at present available suggests that it is the decrease in amount of free mRNA, or the mRNA which is newly formed and unattached to ribosomes, which results in a failure of antigen to induce immunity during the primary exposure to antigen. This is indicated by the specific manner in which actinomycin D produces its inhibitory effect. Antitoxin production during the anamnestic response was inhibited only if the antibiotic had been given during the primary exposure to antigen (Tables 1 and 2). Since RNA extracts from immunized animals have been used to stimulate antibody synthesis in non-immune cells both *in vivo*<sup>17</sup> and *in vitro*<sup>18</sup>, it appears quite possible that the mRNA synthesized during the primary response was utilized as a template for antibody synthesis during the anamnestic response.

Geller and Speirs<sup>6</sup> treated immune mice with daily injections of actinomycin D and were able to demonstrate a rapid high production of antitoxin to a challenging injection. They concluded that the specifically coded mRNA necessary for antitoxin synthesis must have been present in an inactivated form, since in their animals very little circulating antitoxin was present prior to the challenging injection. Fan *et al.* demonstrated that several substances, including chloramphenicol, can inactivate mRNA without resulting in its breakdown<sup>19</sup>, and it would appear quite possible that some component of the antigen could also combine with specific mRNA and thereby temporarily inactivate it. The inactivated mRNA would then be released and re-activated during the events which follow the challenging injection. It is therefore of interest to consider the relationships between antigen and the inactivation and re-activation of RNA.

It has been demonstrated that following injections of radioactive antigen, components of the antigen persist in cells for long periods<sup>7</sup>. Garvey and Campbell<sup>20</sup> noted that the antigen was complexed with RNA and that the complexes retained the capacity for initiating antibody production. Fishman and Adler<sup>21</sup> were able to initiate antibody production in normal rabbits with a ribonuclease-sensitive material extracted from macrophages treated with antigen *in vitro*. These experiments indicate that some antigenic component complexes with RNA resulting in a change in the status of immunity of the cells. Moreover, antigenic material persisting from a primary injection has been shown to undergo degradation during the anamnestic response<sup>22</sup>. This degradation of antigen would presumably cause a release of the complexed RNA, which in the absence of RNase could become attached to ribosomes and induce specific antibody formation. It would seem possible that the period immediately following release of mRNA from antigen complexes, and prior to attachment to ribosomes, would be a vulnerable period. In this regard, it is interesting to note that injections of RNase administered simultaneously with antigen have been found to be an effective suppressant of immunity<sup>16</sup>.

Cells containing radioactive components of antigen participated in the inflammatory reactions produced by later re-injections of a non-radioactive antigen and appeared to be responsible for the specificity of the reactions<sup>7,23</sup>. Primary exposure to antigen could cause an inactivation of the mRNA merely by binding to it and preventing its attachment to ribosomes. Since re-exposure to antigen results in a degradation of the original antigen<sup>24</sup> followed by rapid antibody production<sup>7</sup>, it must be

presumed that the mRNA is released and attaches to ribosomes thereby initiating antibody synthesis. The failure to detect radioactive amino-acid uptake into antibody during the early stages of the anamnestic response<sup>22</sup> indicates that antibody synthesis does not begin immediately but is delayed for a few days. This delay could be explained by the complexing of the antigen with the mRNA freed during the cellular interactions. When all the antigen within the inflammatory cells becomes neutralized or degraded, the mRNA could then attach to ribosomes and initiate antibody synthesis. Since these reactions do not necessitate new synthesis of mRNA, an explanation is obtained for the failure to find an uptake of RNA precursors into plasma cells<sup>23</sup> or for the failure of actinomycin D to block antibody production during the anamnestic response<sup>4,6</sup>. It would appear that the complexing of antigen with mRNA would account for many perplexing immunological phenomena.

The concept that antigen inactivates mRNA can also be extended to include immunological unresponsiveness, if one assumes that mRNA-antigen complexes cannot accumulate in such cells. The capacity to metabolize completely antigen would be characteristic of tolerant and immature cells<sup>24</sup>. Cell multiplication, accompanied by cellular differentiation and specialization, would result in the formation of new types of mRNA, a loss of capacity to detach antigen from RNA, and a transition from tolerance to intolerance. These considerations are important since most theories of immunity cannot satisfactorily explain auto-immunity, or changes in tolerance and immunity to a particular protein<sup>25</sup>.

This work was supported by the Atomic Energy Commission. I am a career scientist of the Health Research Council of New York. The antitoxin assays were carried out under the supervision of Dr. S. Reid and Mr. E. Gentles.

*Note added in proof.* Additional evidence involving preformed RNA in 'immunological memory' and the anamnestic response has become available since submitting this paper for publication. Askonas and Rhodes

(*Nature*, 205, 470; 1965) noted that following a primary exposure to antigen, both antigen and RNA were present in immunogenic extracts of macrophages. In an examination of the secondary response, Kornguth *et al.* (*Exp. Cell Res.*, 37, 650; 1965) demonstrated that increased protein synthesis was not preceded by an increased synthesis of RNA. Further work in our own laboratory indicated that proper timing of the actinomycin D injection could produce complete inhibition of primary immunization at less toxic doses. The maximum inhibitory effect appears to be 1 and 2 days following the antigen injection.

## STRUCTURAL (TRANSLOCATION) HETEROZYGOSITY OVER THREE SUBSEQUENT GENERATIONS IN MAN

By DR. A. GROPP and DR. W. MARSCH  
Pathologisches Institut der Universität, Bonn

AND  
DR. J. BRODEHL  
Universitätskinderklinik, Bonn

CYTOGENETIC studies during the past few years have disclosed various states of balanced or nearly balanced structural heterozygosity in man, leading to unbalanced chromosomal sets in the offspring. Up to now one of the best-known examples is the apparently balanced translocation between one small and one large acrocentric chromosome<sup>1</sup> or between two small acrocentrics<sup>2</sup> and the transmission of this abnormal chromosome to the following generation giving rise to the translocation type of trisomy, No. 21 in Down's syndrome. Edwards *et al.*<sup>3</sup> reported two families with a balanced reciprocal translocation most probably involving the chromosomes No. 4 and No. 9 in one case and No. 1 and No. 6 in the other, both leading to unbalanced karyotypes and abnormal phenotypes in the progeny. Further observations of familial translocation were made by Moorhead *et al.*<sup>4</sup>, Gustavson *et al.*<sup>5</sup>, and recently by Lee *et al.*<sup>6</sup>. The latter authors described a reciprocal translocation in two subsequent generations concerning one chromosome No. 2 and one No. 3 as well as an unbalanced karyotype associated with multiple malformations in the third generation. In all these cases rather large translocated fragments are involved in the balance as well as in the derived unbalanced karyotypes of the offspring.

The report of Schmid<sup>7</sup>, however, on the familial occurrence of a probably translocated additional chromatin piece at a No. 21-22 chromosome, associated with repeated miscarriages, indicates that—depending on the chromosome affected—the exchange of very small fragments can also lead to unbalanced karyotypes with deleterious and lethal effects. Considering that only such chromosomal aberrations as involve clearly identifiable parts of chromosomal material can be detected with our present methods, it may be assumed that structural heterozygosity and its transmission by phenotypically normal carriers, as well as the subsequent origin of unbalanced karyotypes, represents a very important mode of inheritance in man<sup>8</sup>.

Investigating a large family, Walker and Harris<sup>9</sup> provided evidence for the transmission of a translocation between two chromosomes of the No. 13-15 group by phenotypically normal carriers through three subsequent generations. A similar translocation had been described earlier in certain single cases of developmental abnormality<sup>10-12</sup> as well as in a randomly selected male subject<sup>13</sup>. The present report refers to a family with transmission of a structural heterozygosity of a further type through three generations. This condition is present in apparently

Fig. 1. Pedigree of the family

healthy carriers through two generations and in an affected child in the third generation.

The pedigree of the family studied is represented in Fig. 1. Our interest was drawn to this family by the finding of a chromosomal aberration in cultured lymphocytes of a 3-year-old boy (III, 2) showing features of v. Recklinghausen's disease (neurofibromatosis) and marked kyphoscoliosis. He was the first living child of a 25-year-old mother (II, 1) and a 33-year-old father (II, 2). Previously the mother had had a miscarriage with an abortion in the third month (III, 1). The weight at birth was 3,750 g, the length 57 cm. Kyphoscoliosis was first noted when the boy was 6 months old. Later on this alteration grew worse. There were no signs of rickets. At the age of 15 months many café-au-lait spots of the skin were visible. This suggested the diagnosis of neurofibromatosis (v. Recklinghausen's disease), but nodular neurofibromatous lesions were absent.

The later course was characterized by a marked retardation of mental and static development and by insufficient body-weight. The child appears old compared with others of his age-group. He suffers from repeated infections of the respiratory tract.

Lymphocyte cultures were carried out on two different occasions using a modification<sup>14</sup> of the basic method described by Moorhead *et al.* Chromosome counts (Table 1: III, 2) revealed a modal number of 46 chromosomes. Detailed analysis of metaphases indicate a normal XY sex chromosome complement but in all metaphases two abnormal chromosomes, noted as  $T_1$  and  $T_2$ , are very prominent (Figs. 2 and 3). Replacing No. 3 chromosome there is a submetacentric chromosome ( $T_1$ ), resembling the No. 2 chromosome in size and, to some extent, in the location of the centromere. In the 6-X-12 group from the non-paired autosomes one ( $T_2$ ) seems to be abnormal. It is characterized by a pronounced metacentricity and by a small size, scarcely exceeding that of chromosome No. 16.

The same gross chromosomal anomalies were found in the boy's mother (Table 1 and Fig. 3: II, 1), his aunt (Table 1 and Fig. 3: II, 3) and his maternal grandfather (Table 1 and Fig. 3: I, 2). All three are free of any physical or mental disorder.

Chromosomal analysis performed on the boy's unaffected younger sister (Table 1 and Fig. 1: III, 3), father (Table 1 and Fig. 1: II, 2) and maternal grandmother (Table 1 and Fig. 1: I, 3) gave normal results. At the present time the mother (II, 1) is in an advanced stage of a so-far uneventful pregnancy.

Both abnormal chromosomes  $T_1$  and  $T_2$  probably originated by reciprocal translocation, possibly involving

a large part of a chromosome of the 6-12 group and a smaller piece of a No. 3 chromosome. The comparison of the abnormal chromosome  $T_1$  with the normal No. 3 chromosome, particularly considering the location of the centromere, may, however, favour the possibility of an even more complicated mode of origin, comprising perhaps not only reciprocal translocation but also pericentric inversion.

The anomaly in this family can be traced back only to the propositus's grandfather (I, 2). The one living sister of this ancestor could not be investigated. His three deceased brothers were presumably free from developmental disorders.

The transmission of structural heterozygosity in the same, apparently balanced and rather stable combination of the abnormal chromosomes  $T_1$  and  $T_2$ , seems remarkable. It can be assumed that the carriers of the anomaly may produce four types of gametes, one of which will be

Fig. 2. Karyotype from cultured lymphocytes of the propositus (III, 2) demonstrating the two abnormal chromosomes  $T_1$  and  $T_2$ .Fig. 3. Abnormal chromosomes  $T_1$  and  $T_2$ . Compare size with the chromosomes Nos. 2, 3 and 16

	Counted metaphases— No of chromosomes				Total	No. of metaphases analysed in detail
	45	46	47	48

normal, one abnormal but genetically balanced, and two unbalanced. It is of interest to notice that in the third generation different patterns occur: abnormal karyotype (III, 2), normal karyotype (III, 3) and an unidentified (III, 1). This family, however, is too small for investigation by segregation methods.

It is doubtful whether the clinical features of the propositus, who by the finding of the chromosomal anomaly stimulated the family study, can be directly related to this cytogenetic disorder. It is conceivable that the balance of the abnormal karyotype in this boy was disturbed by an additional factor, not detectable cytogenetically. But it is also possible that the co-incidence of the cytogenetic abnormalities and the clinical picture of neurofibromatosis and kyphoscoliosis was by chance. Other cases of v. Recklinghausen's disease do not show chromosomal anomalies (among others, two personal observations). There is a certain analogy between the family described here and reported cases of heritable structural anomalies of chromosomes in healthy or randomly selected persons<sup>15-17</sup>.

Balanced autosomal aberrations, either rather stable or occasionally leading to unbalanced karyotypes in the

offspring, may be more frequent in phenotypically normal human groups than has been suspected.

## SERUM PROTEIN FORMATION OF DONOR TYPE IN RAT-INTO-MOUSE CHIMAERAS

By DR. MILDRED E. PHILLIPS and DR. G. J. THORBECKE

Department of Pathology, New York University School of Medicine

IT has been shown by various authors that serum proteins of donor origin may appear in the sera of lethally irradiated mice protected by heterologous<sup>1-3</sup> or homologous<sup>4,5</sup> bone marrow. Among the proteins which have been identified are  $\gamma$ -globulin<sup>1-3,5</sup>, transferrin<sup>4</sup> and the *S*<sub>2</sub> substance<sup>4</sup>. Grabar *et al.*<sup>6</sup> demonstrated several other proteins of rat origin in sera from rat-into-mouse chimaeras, but the immunoelectrophoretic patterns were not interpreted with respect to identification of individual proteins.

The work recorded here was undertaken in an effort to identify further the donor serum proteins in such chimaeras and to determine their sites of origin. It had previously been found that haematopoietic and lymphoid tissues of mice<sup>7-9</sup> and rats<sup>9</sup> incorporate <sup>14</sup>C-labelled amino-acids into a few serum proteins including the known immune globulins, transferrin,  $\beta_2$ ,  $\alpha_2$ -macroglobulin and, in the case of haematopoietic tissues, the haptoglobin-haemoglobin complex (HpHb). The technique used to demonstrate such <sup>14</sup>C-amino-acid incorporation into individual serum proteins by tissues *in vitro* involves the combination of immunoelectrophoresis with autoradiography<sup>4-9</sup> as applied to concentrated tissue culture fluids.

Rat-into-mouse chimaeras were produced by intravenous injection of  $2-8 \times 10^7$  Sprague-Dawley rat bone marrow cells into CBA or A mice within 4 h after 750-1,000 r. whole-body X-irradiation. The X-irradiation was administered by a Picker therapeutic unit. The dose rate was 42 r./min, at a distance of 45.5 cm from the centre of the animal body. Other conditions were as previously described<sup>10</sup>. Starting a few days before X-irradiation the mice received neomycin in their drinking water, or aureomycin (6 mg/kg/day) in their food. Blood samples were taken at weekly or bi-weekly intervals from the retro-orbital plexus. Sera were analysed by micro-immunoelectrophoresis<sup>11</sup> using absorbed anti-rat sera as described here.

At intervals of 3-7 weeks after irradiation, mice were killed and their livers and spleens removed aseptically. Approximately 50 mg of each spleen or 100 mg of each liver was cultured for 24-48 h at 37° C in roller tubes with 1-2 ml. of medium as previously described<sup>6,9</sup>. <sup>14</sup>C-labelled

lysine and isoleucine (750  $\mu$ c.-1,000  $\mu$ c./mg, Schwarz Biochem.) were added to a concentration of 1  $\mu$ c./ml. each. After the culture period the culture fluids were dialysed against 0.015 M phosphate buffer, pH 7.2, for 48 h, lyophilized, and redissolved with 0.1 or 0.15 ml. of distilled water.

Identification of the labelled rat proteins was accomplished by the use of unlabelled rat carrier serum, which was added to the antigen well of the immunoelectrophoretic slide prior to the addition of the concentrated culture fluid. The immunoelectrophoretic precipitation pattern was developed with rabbit antisera against rat serum and against rat complement, which had previously been extensively absorbed with lyophilized mouse serum and tissues (liver and spleen), and with fresh mouse serum. The anti-rat complement was prepared by immunization of rabbits with a washed immune complex of bovine serum albumin (BSA) and rabbit anti-BSA, which had been incubated with fresh rat serum and then washed again before mixing with complete Freund's adjuvant. For identification of mouse proteins, a mouse serum carrier was used and the patterns developed with a rabbit anti-mouse serum, similarly absorbed with rat serum and tissue powders.

Anti-rat sera absorbed in this manner did not precipitate any serum proteins from sera of normal or irradiated mice. Furthermore, when these anti-rat sera were used to develop an immunoelectrophoretic pattern of rat serum in the presence of highly labelled culture fluids from normal mouse liver or spleen tissue cultures, no labelling of rat serum proteins was observed with the exception of  $\alpha_2$ -macroglobulin in both liver and spleen, and of HpHb in the spleen. This 'non-specific' labelling of  $\alpha_2$ -macroglobulin has been noted repeatedly in previous studies. It occurs with cultures of virtually all living tissues tested, and in all species examined<sup>1-9</sup>. This observation that  $\alpha_2$ M labelling was seen with mouse cultures even in patterns developed by completely absorbed anti-rat sera, strengthens the previous suggestion that the labelling of  $\alpha_2$ M in many tissues is due to a binding to  $\alpha_2$ M of other tissue products, and not to a real synthesis of this protein

Fig. 1. Immunoelectrophoretic patterns of  $^{59}\text{FeCl}_3$  incubated sera from mice 3 days ( $R \rightarrow M1$ ) and 4 weeks ( $R \rightarrow M2$ ) after irradiation and rat bone marrow protection developed by rabbit anti-mouse and absorbed anti-rat sera. Autoradiographs (AR) show absence of rat transferrin at 3 days and presence of a small amount at 4 weeks. In this case the rat transferrin was not visible on the stained slide. Radioactive mouse transferrin is demonstrated in both sera.

by all these tissues. Labelling of HpHb in this system is very difficult to interpret since rat Hp or Hb may bind mouse Hb or Hp, respectively, and thus carry these labelled mouse proteins into the precipitation lines in spite of the use of absorbed anti-rat sera. No such 'non-specific' labelling was observed for  $\beta_{1C-1D}$ , transferrin, or  $\gamma$ -globulin, which are the three major proteins to be reported here.

No sera from mice obtained during the first week after irradiation and bone marrow transfer showed any evidence of containing rat proteins. During the next week, however, most sera began to show an  $\alpha$  line, which sometimes extended into the  $\beta$ -region, giving the typical double-arc appearance of HpHb. This line showed a positive benzidine reaction<sup>18</sup> and could not be demonstrated by antisera which had been absorbed with rat haemoglobin. When used to develop immunoelectrophoretic patterns of normal rat sera, the anti-rat sera were able to react with rat Hp after absorption with rat Hb, and yet they did not show an HpHb complex in the chimaeric sera. It can, therefore, be concluded that the HpHb line seen in

the chimaeric sera consisted of a complex between mouse Hp and rat Hb. The appearance of this line was variable, probably depending on the level of haptoglobin in the serum and on the degree of haemolysis.

Another rat protein, which appeared within 2-3 weeks after the experimental procedure and which could be readily identified, was transferrin (Fig. 1). Incubation of serum with  $^{59}\text{FeCl}_3$  (2  $\mu\text{c./ml.}$ ) resulted in specific labelling of rat as well as of mouse transferrin in the same serum. The serum of 10 animals was specifically examined for the presence of rat transferrin, and positive results were obtained in each case. No rat transferrin was detected in sera taken a few weeks earlier from the same animals.

The majority (18 of 20) of those chimaeras surviving 4 weeks after irradiation had significant quantities of rat  $\gamma_1$ - and  $\gamma_2$ -globulin in their sera (Fig. 2). No evidence was obtained that  $\beta_{1C-1D}$  of rat origin, the major line shown by the absorbed anti-complement sera, occurred in any of the mouse sera up to 7 weeks after irradiation and bone marrow protection.

During the fourth week after the experimental procedure many of the animals succumbed to secondary disease<sup>19</sup>. Most of the animals surviving the secondary disease past the fourth week were killed for tissue culture examination; four mice at 5 weeks, one at 6 and one at 7. Fig. 3 shows the various labelled proteins observed in spleen culture fluids from chimaeras killed 6-7 weeks after irradiation. Among them are  $\gamma_1$ - and  $\gamma_2$ -globulin, transferrin,  $\beta_{1C-1D}$ ,  $\alpha_2$ -macroglobulin, and HpHb. The latter two will not be considered as rat proteins for the reasons already discussed; but the other four proteins appeared to be of rat origin since none of them was labelled when developed with specific anti-mouse sera and mouse serum as the carrier (Fig. 3). One other protein was detected both in

Fig. 2. Immunoelectrophoretic patterns of mouse sera taken 2 ( $R \rightarrow M3$ ) and 4 weeks ( $R \rightarrow M4$  and 4) after irradiation and rat bone marrow protection developed with absorbed anti-rat sera. Note the presence at 2 weeks of some rat  $\gamma$ -globulin, and at 4 weeks of larger amounts of both  $\gamma_1$ - and  $\gamma_2$ -globulins. Rat transferrin can be seen as a small arc in the  $\gamma$ -region (in  $R \rightarrow M3$ , 400). The complex of mouse haptoglobin with rat haemoglobin, most clearly shown by anti-rat serum 2, is seen as a double arc in  $R \rightarrow M4$ .  $\beta_{1C}$  is not present, the line formed by anti- $\beta_{1C}$  is an, as yet, unidentified globulin.

Fig. 8. Autoradiographs from immunoelectrophoretic patterns prepared with rat serum carrier (RS) or mouse serum carrier (MS), and spleen culture fluids from chimaeras taken 6 and 7 weeks after irradiation and rat bone marrow protection. The autoradiograph (A.R., spleen, 7w, bottom) from the specific mouse pattern shows no labelling of any lines, whereas the autoradiographs of the specific rat patterns (A.R., spleen, 6w and 7w, top) show labelling of  $\gamma$ -globulin, transferrin,  $\beta_{10}$  and  $\alpha_{2m}$ .

sera and spleen cultures from several of the chimaeras. This protein cross-reacted with  $\gamma$ -globulin and had a  $\beta_2$  mobility, but needs more precise identification.

The occurrence of rat transferrin and rat  $\gamma$ -globulins in the sera of these chimaeras agrees very well with their production by spleen tissues. These proteins are apparently formed in the mouse spleen by descendants of the transferred rat bone marrow cells. It seems certain that in species such as the mouse and the rat, transferrin is formed by spleen tissue as well as by the liver<sup>4,7,8</sup>, whereas in other species, such as the monkey, human, guinea-pig and sheep, the liver but not bone marrow or spleen incorporates <sup>14</sup>C-amino-acids into transferrin<sup>9,14,15</sup>. Examination of cattle chimaeras also failed to provide evidence of  $\beta$ -globulin (transferrin) production by haematopoietic

cells<sup>16</sup>. Other investigations<sup>9,17</sup> indicate that in the mouse and the rat the synthesis of transferrin by spleen, peritoneal macrophages, and various other tissues, is not correlated with  $\gamma$ -globulin synthesis.

Further work is needed to determine the factors involved in this species difference and the cell type responsible for transferrin production in the spleen.

The specific labelling of rat  $\beta_{10}$  by the spleen cultures agreed with previous findings on the site of  $\beta_{10}$  formation<sup>4,8</sup>, but could not be substantiated by the presence of rat  $\beta_{10-12}$  in the mouse sera. It seems possible that the rate of formation of  $\beta_{10}$  by spleen tissue is too low to lead to detectable serum-levels. Moreover, the presence of secondary disease might have resulted in binding of a portion of newly synthesized  $\beta_{10}$  by antigen-antibody complexes, since  $\beta_{10}$  (O'3) belongs to the complement system<sup>18,19</sup>. The analysis of tissue culture fluids from liver did not reveal the presence of any specific rat serum protein synthesis, whereas various mouse serum proteins, including  $\beta_{10}$ , were actively synthesized by the livers of most chimaeras studied.

We thank Dr. E. K. Rosenberg, Department of Anatomy, New York University School of Medicine, for her assistance with the X-irradiation.

## TURNOVER OF NUCLEAR AND CYTOPLASMIC RIBONUCLEIC ACID AT THE ONSET OF INDUCED AMPHIBIAN METAMORPHOSIS

By DR. J. R. TATA

National Institute for Medical Research, Mill Hill, London, N.W.7

**P**ROFOUND and rapid alterations of the structure and function of almost every type of cell occur when amphibian metamorphosis is precociously induced with exogenous thyroid hormones<sup>1</sup>. Artificial induction of metamorphosis therefore lends itself as a convenient system for investigating the sequential steps involved in the regulation of cellular synthetic process during the later stages of embryonic development. The induction or

accelerated synthesis of several proteins, such as adult haemoglobin, serum albumin, hydrolases and urea cycle enzymes following the administration of L-thyroxine or triiodo-L-thyronine ( $T_3$ ) to American bullfrog tadpoles (*Rana catesbeiana*) has now been well established. There is in this species of the frog, however, a lag period of 60–80 h following hormone administration before newly formed protein or morphological changes can be detected.

Finamore and Frieden<sup>8</sup> observed an increased rate of synthesis of total RNA in the liver of *Rana catesbeiana* tadpoles one day after induction of metamorphosis. In view of the distinct roles of the cell nucleus in RNA synthesis, on the one hand, and of ribosomal RNA in protein synthesis, on the other, I have examined separately the turnover of each of the major types of RNA at the onset of induced metamorphosis. It will be shown in this article that an accelerated synthesis of RNA in the liver cell nucleus and the sequential appearance of newly synthesized RNA in the cytoplasmic ribosomes anticipate the morphological and enzymatic changes in *Rana catesbeiana* tadpoles. The appearance of newly synthesized RNA in cytoplasmic ribosomes is accompanied by an increase in the size and number of polyribosomal aggregates and a more tenacious attachment of the latter to the microsomal membranes. We have also found that a breakdown of part of existing ribosomal RNA accompanies or precedes the appearance of new RNA molecules.

Metamorphosis was precociously induced by the injection of 0.2–0.6  $\mu\text{g}$  of  $T_3$  into *Rana catesbeiana* tadpoles, 6–9 cm long, maintained at 18°–20° in batches of eight animals per 2 l. water. The progression of metamorphosis was followed morphologically by recording the increase in hind-leg length and decrease in tail length, and biochemically by the increase or appearance of adult haemoglobin, serum albumin, liver carbamyl phosphate synthetase and cytochrome oxidase. At varying time-intervals after the induction of metamorphosis, livers were pooled and homogenized in a medium containing 0.33 M sucrose, 0.01 M *tris*-HCl, pH 7.5, 0.05 M KCl and 0.0015 M  $\text{MgCl}_2$ . Nuclei were isolated by the method of Widnell and Tate<sup>9</sup>, and mitochondria, microsomes and the soluble fraction separated from the nuclei-free homogenate by differential centrifugation in the same way as for mammalian tissues<sup>4</sup>. Ribosomes were normally obtained by treating the mitochondria-free supernatant with 0.4 per cent sodium deoxycholate before centrifugation, and in some experiments the concentration of the detergent was varied between 0.1 and 0.5 per cent. 35–45 per cent of total DNA was recovered in the nuclear fraction and 65–80 per cent of total protein and RNA in the cytoplasmic fractions. Polyribosome profiles were obtained by centrifugation of ribosomes through a 15–30 per cent sucrose density gradient<sup>5</sup>, layered over a cushion of 60 per cent sucrose and containing 0.02 M *tris*-HCl, pH 7.6, 0.05 M KCl, 0.0015 M  $\text{MgCl}_2$ , in the SW 25 or No. 30 rotor at 22,000 r.p.m. for 100–150 min. Only ribosomes or RNA adhering to microsomal membranes could sediment through the cushion of 60 per cent sucrose.

RNA synthesis and turnover were examined by the incorporation of 10–15  $\mu\text{Ci}$  of uniformly labelled tritiated uridine (1,220 mc./mM), 2  $\mu\text{Ci}$  of orotic acid- $^{14}\text{C}$  (32.6 mc./mM) or 30–60  $\mu\text{Ci}$  of carrier free  $^{32}\text{P}$  into the different subcellular RNA fractions. RNA was extracted from the 0.4 N perchloric acid-insoluble residue with 2 M sodium chloride at 90° after washing with ethanol and ether. It was separated from DNA by alkaline hydrolysis and ethanol extraction and the radioactivity in the ribonucleotides was measured in a Packard 'Tricarb' liquid scintillation spectrometer for tritium, in a Nuclear Chicago gas-flow counter for carbon-14, and with an end-window Geiger counter for phosphorus-32. Chemical estimation of RNA and DNA was performed according to Burton<sup>6</sup> and Ceriotti<sup>7</sup>, protein by the method of Lowry<sup>10</sup> and phosphorus by that of Fiske and Subbarow<sup>11</sup>.

Table 1 shows that the time that elapsed between the administration of  $T_3$  and the first observation of some morphological and biochemical changes which characterize metamorphosis under our experimental conditions is of the order of 65–100 h. A similar lag period preceding the morphological changes or increase in enzyme activity has also been observed by other workers in precocious  $T_3$  or thyroxine-induced metamorphosis in *Rana catesbeiana* tadpoles<sup>1,12</sup>. During this period there was little or

Table 1. LAG PERIOD BETWEEN  $T_3$  INJECTION AND APPEARANCE OF SOME MORPHOLOGICAL CHANGES AND INCREASED SYNTHESIS OF PROTEINS AND ENZYMES

	Lag period (h)
Adult haemoglobin appearance	92 $\pm$ 12
Serum albumin increase	105 $\pm$ 10
Liver carbamyl phosphate synthetase	77 $\pm$ 7
Tail acid phosphatase	65 $\pm$ 6
Tail resorption	68 $\pm$ 8
Hind-leg growth	75 $\pm$ 10
Cytochrome oxidase in liver mitochondria	88 $\pm$ 10

Time that elapsed before a 10 per cent increase or change relative to control values was observed.

no change in the weight, or total protein and DNA content of the liver.

Preliminary investigations with phosphorus-32, tritiated uridine and orotic acid- $^{14}\text{C}$  showed that all these precursors were incorporated more slowly into all types of RNA of tadpole liver than in mammalian tissues. Optimal labelling of the 'rapidly labelled RNA' in the nucleus, with little radioactivity in the cytoplasmic RNA, was obtained only at 70–120 min after the administration of the labelled precursors. Virtually no label was found to be incorporated into liver DNA of either control tadpoles or up to 10 days after the induction of metamorphosis. Fig. 1 shows that the specific radioactivity of 'rapidly labelled' RNA in nucleus was considerably enhanced in those animals in which metamorphosis had been induced 25–30 h before the administration of tritiated uridine. If the animals were killed at later time-intervals after the administration of the radioactive label, RNA of increasing specific radioactivity was recovered in the mitochondrial and microsomal fractions with a fall in the radioactivity of nuclear RNA. The effect of induction of metamorphosis

Fig. 1. Specific radioactivity of nuclear, soluble and microsomal RNA in liver of tadpoles killed at different time-intervals after the induction of metamorphosis with  $T_3$ . All animals received 10  $\mu\text{Ci}$  of tritiated uridine 100 min before they were killed. ●, Nuclear RNA; ○, soluble RNA; △, microsomal RNA.

Fig. 2. Ratio of specific radioactivity of liver nuclear, ribosomal and soluble RNAs of induced/uninduced tadpoles at different time-intervals after  $T_3$  administration. All animals were killed 10–5 h after receiving 65  $\mu\text{Ci}$  of  $^{32}\text{P}$  (add 10.5 h to times indicated on abscissa for total time elapsed after the hormone was given).

on the 'slowly labelled' RNA was to enhance the incorporation of the precursor not only into nuclear but also into cytoplasmic RNA. This is illustrated in Fig. 2 for an experiment in which animals at different stages after induction of metamorphosis were killed 10.5 h after phosphorus-32 was administered. The failure to observe the enhanced synthesis of all species of RNA 5 or 6 days after T<sub>3</sub> administration was due to the dilution of phosphorus-32-labelled precursor by the rapid release of nucleotides, etc., from the regressing tail and intestine. Otherwise, all isotope experiments have shown that the first signs of induced metamorphic changes in the liver are preceded by 20-30 h by an enhanced synthesis of nuclear RNA which is soon followed by the appearance of newly formed RNA in the cytoplasm.

There was no substantial net accumulation of nuclear RNA during the first 140 h after metamorphosis was induced and only a slight accumulation of ribosomal RNA after 75 h, thus suggesting an accelerated turnover of RNA in view of the increased specific radioactivity. The following are the actual values: 0.25-0.40 mg nuclear RNA/mg DNA, 1.08-1.62 mg ribosomal RNA/g liver, and an RNA:protein ratio in ribosomes of 0.18-0.24. Pina-more and Frieden<sup>8</sup> had also reported no change in total liver RNA under comparable conditions.

Evidence that the increase in RNA synthesis at the early stages of induced metamorphosis was accompanied by an accelerated breakdown of 'old' ribosomes was provided by an experiment in which ribosomes were labelled with tritiated uridine 5-8 days before induction. Administration of T<sub>3</sub> to tadpoles with pre-labelled ribosomes was followed 24 h later by a 20-30 per cent drop in the radioactivity recovered in ribosomal RNA, compared with a rate of loss of 2-5 per cent of the label/24 h in the uninduced controls. The specific radioactivity was, however, lowered by only 5-10 per cent. The reduction in radioactivity of ribosomal RNA was accompanied by an increase in the specific radioactivity of nuclear RNA, thus suggesting a re-utilization of the degradation products. In fact, the total radioactivity in the tissue remained virtually unchanged during the first 2-3 days after the induction of metamorphosis.

With regard to the nature of newly synthesized RNA appearing in the cytoplasm at the same time as the degradation of 'old' ribosomes, we have separated the 78S ribosomes from the polyribosomal aggregates by sucrose density gradient centrifugation<sup>8</sup> in experiments in which the RNA was labelled after induction of metamorphosis.

The results of a typical experiment (Fig. 3) illustrate the following features: (1) The relative fraction of total ribosomes recovered as polysomes from the livers of metamorphosing tadpoles is about twice that from those of control animals. This finding suggests an increase in messenger RNA content, size or stability during metamorphosis<sup>8,11</sup> (note, however, that tadpole liver preparations contain a higher amount of monomeric 78S ribosomes than mammalian liver preparations<sup>8</sup>). (2) In control animals (Figs. 3A and C) the specific radioactivity of RNA recovered in the polysomes was greater than in the monomers both after short (4.5 h) and long (20 h) periods of labelling, suggesting that prior to metamorphosis messenger RNA may appear more rapidly than ribosomal RNA in the cytoplasm. However, during metamorphosis the specific activity of the monomers and aggregates increased in a parallel fashion, especially as seen after long exposures to tritiated uridine (Fig. 3D). This pattern

was seen over a wide range of time-intervals after induction of metamorphosis, and one explanation of this may lie in the possibility of new ribosomes being 'pre-coded' with messenger RNA before being released into the cytoplasm as has been suggested by Nirenberg<sup>12</sup>. Extraction of RNA from ribosomes and analysis by sucrose density gradient centrifugation gave compatible results, except that a much higher fraction of RNA in all cases was recovered as low molecular weight components (4S-10S) than that reported for mammalian liver<sup>13</sup>. (3) A greater fraction of ribosomes was recovered in the membranes sedimenting through the dense 60 per cent sucrose after induction of metamorphosis, when the same amount of detergent was used per unit RNA to release ribosomes from microsomes. A higher concentration of deoxycholate was necessary to get almost complete release of ribosomes and polysomes in preparations from metamorphosing animals and, after correcting the extinction at 260 mμ for the higher protein content of the membranes, a substantial part of the membrane-bound RNA was newly synthesized. Thus, during metamorphosis there occurs a firmer attachment of ribosomes to the endoplasmic reticulum or an enhanced synthesis of the latter, which is interesting in view of Hiatt's<sup>14</sup> suggestion that the site of cytoplasmic protein synthesis *in vivo* is the polyribosomes attached to the membranes of the endoplasmic reticulum. The accelerated synthesis of new ribosomal RNA at the onset of biological actions of developmental hormones, such as oestrogen, testosterone and thyroid hormones, has also been reported in mammalian systems<sup>15</sup>. It is possible that the formation of new ribosomes may be important for the expression of

Fig. 3. Distribution of tritium-labelled RNA in monomeric ribosomes (78S) and polyribosomal aggregates in liver ribosomes pooled from 10 tadpoles per group in which metamorphosis was induced (B, D) or not (A, C). Metamorphosis was induced by an injection of 0.5 μg T<sub>3</sub> 116 h before killing; half the animals were injected with 10 μc of tritiated uridine 4.5 h (A, B) and the other half 20 h (C, D) before killing. Ribosomes from 300 to 500 mg liver were layered over a 15-30 per cent sucrose gradient (containing 0.05 M KCl, 0.02 M Tris-HCl buffer, pH 7.6, 0.0015 M MgCl<sub>2</sub>), with a cushion of 60 per cent sucrose at the bottom of the tube, and centrifuged in a No. 30 Spinco rotor at 25,000 r.p.m. for 2.2 h. 1 ml. fractions were collected from which aliquots were taken for the measurement of O.D. at 260 mμ (—) and for the determination of radioactivity present as RNA (---). Direction of sedimentation is from right to left; upward pointing arrows indicate the interface between the 60 and 80 per cent sucrose layers. Note that the 78S ribosomes (downward pointing arrow) have not been clearly separated from the dimeric forms. The pellet at the bottom of the tube, which consisted of membrane-bound RNA, was treated with 1 per cent sodium deoxycholate before determination of optical density and radioactivity in RNA.

newly synthesized messenger RNA necessary for producing the developmental changes that are hormone-dependent.

In conclusion, these experiments have shown that the biochemical and morphological changes of thyroid-hormone induced metamorphosis in *Rana catesbeiana* are anticipated by 24 h by an enhanced synthesis of RNA in the nucleus of the liver which is actively engaged in the synthesis of several new proteins. Activation of nuclei is followed by an accelerated rate of formation of cytoplasmic ribosomal and polyribosomal RNA and a more rapid rate of degradation of ribosomes that were present before the induction of metamorphosis. A firmer binding of ribosomes to the membranes of the endoplasmic reticulum also accompanied the appearance in the cytoplasm of newly synthesized RNA. There is, however, a relatively long lag period of 25-30 h between the time of induction of metamorphosis and the acceleration of RNA synthesis in the nucleus. The mechanisms regulating RNA synthesis and turnover during this initial period, and which respond to the hormonal stimulus for metamorphosis, still remain to be identified.

I thank Mr. A. J. Bell for his assistance.

## PROPERTIES OF HORSE SERUM GAMMA INHIBITOR

By DR. F. BIDDLE, D. S. PEPPER AND PROF. G. BELYAVIN

Department of Bacteriology, University College Hospital Medical School, London, W.C.1

HORSE serum has been shown to be capable of inhibiting the haemagglutinating action and infectivity of the Asian influenza viruses<sup>1,2</sup>. Attempts have been made to separate the active material ( $\gamma$ -inhibitor) from horse serum, and preparations have been obtained which vary in their electrophoretic mobility and in their sedimentation properties. Thus Křižanová-Laušková *et al.*<sup>3</sup>, by precipitation with 'Neokal' and sulphosalicylic acid and by phenol extraction, obtained two inhibitory preparations, one component moving electrophoretically with the  $\alpha$ -globulins and having an  $S_{20}$  of 3.66 and two components moving just ahead of the  $\gamma$ -globulin and having  $S_{20}$  values of 14.7 and approximately 5.9. Later Křižanová and Lesko<sup>4</sup> reported the isolation of three components moving on electrophoresis with the  $\alpha$ -globulins and with  $S_{20}$  values of 8.6, 3.4 and 2.8. Boretti *et al.*<sup>5</sup>, using a sequence of precipitation methods, also obtained three components with inhibitory activity, and  $S_{20}$  values of 8.7, 17.5-21, and 39.8.

Although none of these sedimentation constants appears to be an extrapolated value, the variation seems sufficiently great for it to be difficult to reconcile all the results so far reported, with the concept that  $\gamma$ -inhibitor is one single substance or group of substances. Recent work in this laboratory<sup>6</sup> makes it clear that the method used in fractionating the serum determines the apparent distribution of inhibitory activity; where relatively mild methods are used the inhibitory activity is confined exclusively to the  $\alpha$ -globulin fraction of the serum. In the present article it is shown that if separation is carried out with due regard to the correct ionic strength and pH, the majority of the inhibitory activity appears to be carried by a single fast-sedimenting component (extrapolated  $S_{20}$  = 18.0) with the electrophoretic mobility of an  $\alpha_2$ -globulin.

Fifty-ml. quantities of freshly clotted horse serum were spun on a Spinco model L centrifuge at 40,000 r.p.m. (40 rotor) for 20 h. The supernatant was removed and the sedimented pellets frozen. The frozen pellets could be easily removed from the 'Lusteroid' tubes by eliciting and were transferred to a dialysis sac and dialysed against 0.15 M barbiturate buffer pH 8.6. The final volume was adjusted to 10 ml., transferred on to an inert cellulose column 42 cm long (LKB column electrophoresis model

3340) and electrophoresis carried out in 0.15 M barbiturate buffer pH 8.6 using a current of 60 m.amp and a potential of 410 V, for 22 h. The column was then eluted with the same buffer and 5-ml. fractions were collected and tested for inhibitory activity against 8 agglutinating doses of influenza A<sub>1</sub> virus by the standard 'pattern' method, and for protein content by measuring extinction at 280 m $\mu$ . Although the column was grossly overloaded by the quantities used, the inhibitor could be well localized. All fractions giving an inhibitor titre > 80 were pooled, dialysed against 0.15 molar saline and concentrated by dialysis against 20 M 'Carbowax'. The final volume of concentrate was adjusted to 8.6 ml., and on sedimentation in a Measuring and Scientific Equipment analytical ultracentrifuge at a total protein content of 0.5 per cent showed two major peaks (Fig. 1), which were calculated to have  $S_{20}$  values of 6.03 and 14.70.

In the next stage, 2 ml. of the concentrate from electrophoresis was layered on to a sucrose density gradient (45 per cent-9 per cent in 0.15 M sodium chloride solution) and centrifuged in a Spinco SW 25 rotor at 25,000 r.p.m.

Fig. 1. Schlieren pattern from analytical ultracentrifugation of electrophoresis preparation 28 min after reaching a speed of 57,140 r.p.m. Angle, 80°. Total protein concentration, 0.5 per cent. Sedimentation towards left.

for 30 h. Two distinct bands (Fig. 2) were produced and 1-ml. fractions were collected by tube puncture and tested for inhibitory activity and protein content. The results (Fig. 3) show that up to 80 per cent of the inhibitory activity recovered on the gradient is carried with the 'fast'-sedimenting band. The fractions corresponding to the two bands were pooled, dialysed against 0.15 M sodium chloride again and re-run in the analytical ultracentrifuge after concentrating with 'Carbowax'. Fig. 4 shows the appearance of the material from the 'fast'-sedimenting band. It will be seen that apart from the expected 'fast'-moving peak (extrapolated  $S_{20,w} = 18.0$ ) there is also a small, slowly sedimenting peak ( $S_{20,w} = 6.33$  at a single concentration of 0.5 per cent total protein). This is probably due to incomplete resolution on the gradient.

Fig. 4. Schlieren pattern from analytical ultracentrifugation of 'fast' band derived from density gradient, 28 min after reaching speed of 59,820 r.p.m. Angle, 70°. Total protein concentration, 0.33 per cent w/v. Sedimentation towards left

Fig. 5. Distribution of inhibitory activity and protein extinction in density gradient fractions of original horse serum

Table 1 gives the results of one experiment in which the percentage recovery of inhibitory activity at each stage is calculated with reference to the original serum, and also shows the specific activity in terms of haemagglutination inhibition (H.I.) titre per mg of nitrogen. In nine subsequent experiments the recovery of inhibitory activity in the 'fast'-moving band ranged from 55 to 80 per cent of the total activity in the serum.

In connexion with the foregoing, certain points are of great importance. First, the authors quoted here used fairly drastic methods of separation and attention has already been directed to the problems of using such

Table 1. INHIBITORY ACTIVITY RECOVERED AT EACH PREPARATIVE STEP

Material	Specific activity (H.I./mg nitrogen)	Recovery of inhibitory activity (per cent)
Original serum	30	—
Centrifuged concentrate	70	96†
Electrophoresed prep	100	120
'Fast' peak	1,600	87

\* Referred to original serum

† Error of test  $\pm 25$  per cent.

methods. Secondly, previous workers dialysed their products against water at some stage in the procedure. It has been established in this laboratory that if solutions of <0.08 ionic strength are used the inhibitor precipitates out and cannot be completely recovered. Furthermore, there is often a fall in inhibitory activity of the recovered material and this is then very liable to undergo irreversible precipitation. It has also been found that ionic strengths >3 caused a similar effect. In the present work care was taken to work with electrolyte solutions about 0.1–0.15 ionic strength.

It seems likely that the 'slow'-moving components obtained by other workers represent breakdown products of the naturally occurring 18S material, and in our investigations we have seen such a breakdown occurring when potassium tartrate gradients (40–8 per cent) were used. In these cases early denaturation was indicated by a 'fast'-moving band which had intense light-scattering properties and in some of these preparations biological activity was found distributed throughout the length of the gradient.

Thus it appears that the bulk of the  $\gamma$ -inhibitory activity of horse serum is associated with a 'fast'-sedimenting molecule having the electrophoretic mobility of an  $\alpha_2$ -globulin. The subsidiary shoulder of inhibitory activity seen on density gradient centrifugation of the electro-

phoresed portion seems to represent a second molecular species which is present in the original serum and is possibly generated by breakdown of the larger molecule. Density-gradient centrifugation of the original serum before separation of the active components gave the results shown in Fig. 5. The greater part of the inhibitory activity will be seen to be ahead of the main protein band, but there is again a shoulder of activity similar to that seen after separation. It appears that unless operations are carried out in solutions of ionic strength about that of physiological saline such breakdown is considerably accelerated.

We thank the Wellcome Trust and the Fleming Memorial Fund for the purchase of essential equipment. We also thank Mr. F. Clothier (Medical Research Council, Carshalton) for help with the analytical ultracentrifugation, and Measuring and Scientific Equipment, Ltd., for allowing us the free use of their analytical ultracentrifuge.

## ROLE OF A STRUCTURAL GLYCOPROTEIN OF CORNEAL STROMA IN TRANSPLANTATION IMMUNITY

By DR. L. ROBERT, P. PAYRAU, Y. POULIQUEN, J. PARLEBAS and B. ROBERT

Centre de Recherches Allergiques et Immunologiques, 96, rue Didot, et Fondation E. de Rothschild pour l'Ophthalmologie, Paris

**I**SOLATION and characterization of the so-called 'transplantation antigens' are among the major tasks for those studying the problem of histocompatibility. Most effort has been directed towards intracellular proteins isolated from different tissues<sup>1,2</sup>. It appeared interesting to us to explore the possible role of the structural proteins of connective tissue. Cornea was chosen as a model system because of the relatively high percentage of healing ('take') of homo- and even hetero-grafts and because of the abundance of experimental work that has been reported on keratoplasty<sup>3,4</sup>.

We recently isolated a 'structural glycoprotein' from cornea, keratoglycosaminoglycan-I (KGAG-I), which is associated with the insoluble collagenous network of the corneal stroma<sup>5,6</sup>. An immunochemically identical protein is present in the soluble extracts (pro-KGAG) and according to labelled amino-acid incorporation data it behaves as a metabolic precursor of the structurally linked KGAG. Though the isolation procedure first used is a rough one, the preparation obtained from insoluble stroma still behaves as a good antigen and seems to be identical with one at least of the organ- and species-specific antigens of corneal stroma<sup>7-9</sup>.

It could be shown by the immunofluorescent method that this glycoprotein is exclusively localized in the stroma, no detectable amounts being present in the cellular layers of the cornea<sup>5</sup>. Pure KGAG as obtained by the urea extraction procedure<sup>10</sup> gives rise to antisera (in rabbits and chicken) showing sometimes extended cross-reactions between different species<sup>7,8</sup>. The experiments reported here suggest that some parallelism can be established between *in vitro* immunochemical cross-reactions and the *in vivo* reactions observed in pre-immunized animals grafted with homologous and heterologous tissues. They indeed show a parallelism between circulating antibody titres and the intensity of the reaction against the graft. Rabbits were immunized with different

preparations of calf and rabbit cornea as follows. 5 mg of protein was injected with Freund's incomplete adjuvant 3 times a week for 2 weeks. Then 10 mg of protein was injected with the same adjuvant 3 times a week for 2 further weeks. After 1 week of interruption a booster shot was given (10 mg protein). Blood was taken weekly from the ear vein and the anti-KGAG antibody titre established by passive haemagglutination as described<sup>7</sup>. The preparations used for immunization were<sup>9</sup>: (1) pure KGAG prepared from the insoluble corneal stroma by urea extraction, after removal of the collagen by hot TCA<sup>5</sup>; (2) the 'crude soluble collagen' obtained by precipitating it from the calcium extracts of cornea by dialysis; and (3) the soluble proteins of the cornea (OTC-extract), the supernate of the dialysed calcium extract.

One week after the last injection the animals received grafts. All the grafts were of the intralamellar type<sup>4</sup>. The epithelium of the corneal grafts was scraped off in order to eliminate the reaction to the epithelial proteins<sup>5</sup>. The behaviour of the grafts was then closely followed by daily observation using a slit lamp and photographic recordings. Table 1 shows the results obtained.

In the third row of Table 1 are given the circulating antibody titres determined at the end of the immunization period, on blood taken before the day of grafting. The anti-KGAG titres vary according to the antigen used for immunization<sup>7</sup>, the highest titres being obtained when pure KGAG is used as an antigen.

In the control animals the homografts were accepted, without any reaction, within the 8 weeks of observation. The heterografts also gave good results, though in four animals a slight vascularization and transitory opacity was seen during the fifth week after grafting.

In all the animals immunized with calf corneal preparations there was a strong reaction against the heterograft. The time of onset varied from 1 to 3 weeks. Heavy vascularization, pannus formation and severe opacity

Table 1. REACTION OF RABBITS TO CORNEAL HOMO- AND HETERO-GRAFTS (CALF CORNEA)  
Effect of immunisation with corneal extracts. Homograft on left eye and heterograft on right eye

No.	Immunising antigen	No. of anti- male	Circulating antibody titre* $\times 10^{-4}$	Intensity† of reaction to Homograft		Intensity† of reaction to Heterograft

6	KGAG of calf cornea	3	3,200-12,800	0	± (3)	+++	+++ (5)
7	CSO of rabbit cornea	3	128-1,024	+	+(1)	+	+(2)
8	KGAG of rabbit cornea	2	5,100-10,200	0	± (1)	++	++ (1-3)

\* Determined on blood drawn the day before grafting, with red cells coated with calf-KGAG. The figures represent extremes of haemagglutination-titres found in the different animals.

† The intensity of the vascular-inflammatory reaction and of the opacity is given by the number of plus signs. The figure in parentheses after the sign is the time of onset of the opacity in weeks. The reactions were identical or very similar in intensity in the animals of the same group.

‡ Soluble proteins of the corneal stroma, extracted in Ca-tris-citrate (CTC) buffer.

§ 'Crude soluble collagen' of corneal stroma.

of the heterografts were always observed. The homografts were unaffected except for two of the animals treated with calf-KGAG. In these animals a transient and light opacity of the homograft was observed on the third week after grafting, which disappeared in 5-10 days. This contrasted with the strong and definitive opacity observed in the heterografts.

The rabbits immunized with homologous corneal extracts did not produce antibodies against rabbit-KGAG, except in one case where the titre rose to 1/160. There appeared, however, circulating antibodies detectable with red cells coated with calf-KGAG (see Fig. 1). This phenomenon was observed with all the rabbits immunized with homologous corneal preparations (both crude soluble collagen (CSO) and pure KGAG). In the control animals treated only with Freund's incomplete adjuvant no such reaction could be observed. The haemagglutination gave low but comparable titres with red cells coated with either rabbit or calf KGAG (see Fig. 1).

In agreement with the serological observations (see Table 1) strong reactions were obtained against the calf-grafts in these rabbits treated with rabbit corneal extracts with 'early opacity of the grafts (1-3 weeks).

No reaction, or only a mild and transitory one, could be observed on the cornea that received the homografts. These reactions were somewhat stronger than those observed in the unimmunized control group where transi-

tory inflammatory reactions with opacity could be observed on the first week in some animals, which disappeared on the second or third week.

These results suggest the following interpretation. It is now generally recognized that late clouding of corneal grafts is a result of an immune reaction<sup>10</sup>. Though many antigenic components were demonstrated in cornea<sup>11</sup>, those directly responsible for such reactions have not yet been isolated and identified. Our experiments show that the structural glycoprotein, KGAG, probably has an important role as a mesenchymal antigen in 'immune-recognition-reactions' which occur after keratoplasty. The presence of circulating antibodies against this protein produces a highly accelerated immune reaction against a heterologous tissue implanted even in such an avascular site as the cornea (all the grafts were of the intralamellar type). The highest titres of antibodies and the strongest reactions are obtained when pure KGAG, extracted from the insoluble stroma, is the immunizing antigen. The CTC extract, which has many other soluble proteins beside the precursor-form of KGAG (pro-KGAG), produced antibodies of a low titre and a milder reaction than either the 'crude soluble collagen' fraction (CSO) or the KGAG extracted from insoluble stroma.

The very existence of the phenomenon of late clouding of corneal grafts suggests the importance of insoluble antigenic components. The soluble proteins must have disappeared from the graft by the time the late clouding sets in<sup>3</sup>. A slow solubilization of structurally linked components such as KGAG, however, might well explain the late onset of the immune reaction. When rabbits are immunized with calf or horse cornea preparations the antisera obtained react with rabbit-KGAG also<sup>8</sup>. In spite of this we could not obtain high-titre antisera against rabbit-KGAG by direct immunization of rabbits with homologous corneal preparations. The appearance of antibodies detectable with calf-KGAG-coated red cells can be explained in several ways. A plausible hypothesis would admit that antibody production takes place when immunizing with rabbit cornea, but those antibodies strongly specific to rabbit-KGAG are adsorbed on to identical or cross-reacting structures present in different organs<sup>12</sup>. Only those antibodies with a pronounced specificity to cross-reacting organ-specific sites would remain in the circulation. This explanation is in agreement with the known heterogeneity of the antigenic and antibody sites and with the presence of identical or cross-reacting structures, similar to KGAG in other organs as revealed by immunofluorescence<sup>8</sup>. The slight but definite reaction to homografts and the strong reaction to the heterografts are also in accordance with such an explanation. The homograft would be 'protected' in a way by the presence of cross-reacting (or identical) substances present in other mesenchymatous tissues.

These results, as well as others obtained with pig corneas<sup>11</sup>, suggest the importance of KGAG as a specific antigenic component operating in species-recognition reactions.

The accelerated rejection of intralamellar grafts obtained by immunization with a pure mesenchymal protein suggests that besides the intracellular 'transplantation antigens', connective tissue also carries species-specific antigens. Though the intracellular antigens may be predominant when highly cellular tissues are transplanted, mesenchymal antigens can play an identical part when acellular and avascular tissue, such as corneal stroma, is transplanted. It may be of importance in this respect that KGAG exists in a soluble, 'precursor' form<sup>13,14</sup> and also as an insoluble, structurally linked component of connective tissue. The soluble form may be of major importance in producing sensitization in the host, and the insoluble form would then act as a target for the antibodies and for the sensitized cells. The part of KGAG and of related 'structural glyco-proteins' in immune-recognition reactions in general is now being investigated.

Fig. 1. Anti-KGAG antibodies in the blood of rabbits immunized with rabbit corneal preparations. The immunising antigen is indicated on the right side of the graph. The antibody titres (as obtained by passive haemagglutination) are given as their negative logarithms on the left of the graph. Determinations were done simultaneously with red cells coated with rabbit-KGAG and with calf-KGAG. Unshaded areas, anti-rabbit KGAG antibodies, shaded areas, anti-calf KGAG antibodies

In a previous report, cleavage of sodium dodecyl sulphate by a bacterial enzyme system was measured by following the accumulation of sulphate ion via the barium chloride procedure<sup>1</sup>. However, the sensitivity of this method was so low that several  $\mu\text{mole/ml}$  of detergent

**Detergent-methylene blue complex method (complex method).** The main procedure of this new method is the spectrophotometric measurement of the amount of methylene blue released from a dye-detergent complex. (Fig. 1)<sup>8</sup>. Advantage is taken of the chloroform solubility of a dye-detergent complex to separate free, water-soluble methylene blue from that portion of the dye still bound to the detergent. During enzymatic splitting of the detergent, an equivalent quantity of dye is released from the complex and the measurement of this released dye constitutes the basic parameter. This is shown schematically as:

Fig. 1. Methylene blue-detergent complex method. Free water-soluble methylene blue was released from chloroform-methylene blue-detergent complex as the result of enzyme action. To 85 mmole/ml sodium dodecyl sulphate in 0.05 M tri-*n*-hydrochloride (pH 8.0) containing 0.14 M sodium chloride (*trw* 8-9), aqueous  $10^{-4}$  M methylene blue slightly in molar excess was added so that after extraction with one volume of chloroform, the optical density at the aqueous phase was 0.05-0.1. It was important to avoid an excess of sodium dodecyl sulphate to prevent the destruction of the enzyme. The enzyme solution was added to the reaction mixture and extracted at 35° C in a water-bath shaker operated at 100 r.p.m. In order to avoid a possible photodynamic action of methylene blue, the reaction was carried out in the dark. At appropriate intervals, 10 ml. of the reaction mixture were removed and immediately extracted with 10 ml. of chloroform. Multiple extraction with chloroform was not found to be necessary. The colour intensity in the resulting aqueous phase was determined in a spectrophotometer at 560 m $\mu$  using 1.75-in. test-tube. The absorbancy in such a test tube was converted to  $\mu$ mole/ml. of methylene blue concentration by using the factor of 25, since 10  $\mu$ mole/ml. of methylene blue in water have an absorbancy of 0.4.

**Barium chloranilate method.** This method is based on the reaction shown in Fig. 2. Water-insoluble barium chloranilate (2,5-dichloro-3,6-dihydroxy-*p*-benzoquinone barium salt), when combined with free sulphate ions in

**Fig. 2. Barium chloranilate method.** An assay of sulphate released from the detergent as the result of enzyme action. Each 1.5 ml. of the final reaction mixture contains 15  $\mu$ moles of SDS (0.16 ml. of 0.1 M), 0.15 ml. of 5-7 per cent bovine serum albumin dissolved in 0.06 M trihydrochloric acid buffer (pH 8), the enzyme solution and 0.05 M trihydrochloric acid buffer (pH 8) containing 0.14 M sodium chloride (tris 8-8). It is important to mix sodium dodecyl sulphate and bovine serum albumin solution thoroughly before adding the enzyme solution (1). After the enzyme solution was added, the reaction mixture was incubated at 37° C in a shaker. At the end of the incubation period the reaction was terminated by adding 1 ml. of 0.5 M potassium biphenylate and 2.5 ml. of 95 per cent ethanol. The mixture was then heated in a water bath at 70° C for 10 min. The resulting precipitate was eliminated by centrifugation. The supernatant was then transferred to a 125-ml. flask and 20 mg. of barium chloranilate was added. After 15 min. of incubation in a shaker at 37° C, the remaining barium chloranilate and resulting barium sulphate were eliminated by centrifugation. The pink-coloured chloranilate ion was read spectrophotometrically at 510 m $\mu$  of wave-length. Ten  $\mu$ moles/ml. of sulphate ion has 0.85 absorbancy in 1-cm optical path cuvette.

Fig. 3. Comparison of the complex method with the barium chloranilate method. Varied amounts of enzyme previously assayed by the barium chloranilate method were incubated at  $32^{\circ}\text{C}$  with 33 mMoles/ml. of sodium dodecyl sulphate which were mixed with equal molar of methylene blue in 0.06 M Tris 8-8. The figures on each curve represent the partially purified enzyme activity in millunits per ml. assayed by the barium chloranilate method. The enzyme activity measured by the complex method is shown in the ordinate. The intensity of methylene blue colour in water phase after extraction with chloroform was measured at a wave-length of 690 m $\mu$ .

the presence of acid, releases water-soluble chloranilate ions. This results in a solution having a pink colour<sup>4</sup>.

**Definition of unit and specific activity.** One unit of enzyme is defined as: (a) that amount capable of forming 1  $\mu$ mole of sulphate ions by the barium chloranilate method, or (b) the amount which will catalyse the release of 1  $\mu$ mole of methylene blue in 1 h at a temperature of  $32^{\circ}\text{C}$ , and at pH 8 by the complex method.

**Comparison of complex method and barium chloranilate method.** A solution of partially purified enzyme<sup>2</sup> was assayed by the barium chloranilate method and found to contain 60 units/ml. Various dilutions of this enzyme were assayed by the complex method. In a proper dilution of the enzyme solution, the curve showing the amount of dye released with respect to the time was found to be linear. The activity of the enzyme was calculated from the linear portion of the curve. As shown in Fig. 3, 12 millunits per ml. of enzyme assayed by the barium method were observed as against 17 millunits per ml. at 60 min observed by the complex method. The activity assay by the complex method tended to be slightly higher than that measured by the barium chloranilate method. This could be partly due to the high concentration of detergent used in the barium chloranilate method, which tends to destroy the enzyme activity even though the destroying action was counteracted by using bovine serum albumin.

**Molar ratio of methylene blue to sodium dodecyl sulphate in substrate.** The molar ratio of sodium dodecyl sulphate to methylene blue was varied from 1:1 to 2:1 and 3:1. The three mixtures were subjected to constant amounts of the enzyme action. The results shown in Fig. 4 suggest that in the mixture having a ratio of one methylene blue to sodium dodecyl sulphate colour was released into the water phase immediately after reaction with the enzyme. In the mixtures having more sodium dodecyl sulphate the release of the methylene blue colour into the water phase was delayed for a period determined by the quantity of excess detergent. It appears that when excess sodium dodecyl sulphate was present either the enzyme preferred the excess free sodium dodecyl sulphate, or else it digested the sodium dodecyl sulphate complexed with methylene

blue, thereby releasing the latter, which then re-formed additional complexes with unreacted sodium dodecyl sulphate.

Although the new complex method has been used only to assay sodium dodecyl sulphate splitting enzyme and intact cells, it might also be applied to the splitting of other anionic detergents, such as alkyl benzene sulphonate.

The advantages of the complex method over the barium chloranilate method are: (1) the complex method is very much more sensitive than the barium chloranilate method; (2) the contamination of the detergent by sulphate does not appreciably interfere with the complex method; (3) the assay by the complex method takes less time; (4) the increased sensitivity of the method permits the use of a much lower detergent concentration than in the barium chloranilate method, thereby reducing the destruction of the enzyme by the detergent and also reducing the need for protective bovine serum albumin.

**Sodium dodecyl sulphate splitting activity of intact cells.** An experiment assaying the detergent-splitting activity of intact *Pseudomonas* was conducted using the sensitive

Fig. 4. Varied molar ratio of methylene blue to sodium dodecyl sulphate. Methylene blue was mixed with varied molar ratio of sodium dodecyl sulphate and incubated with constant amount of partially purified enzyme. The amount of methylene blue released from dye-detergent complex was assayed by the complex method.

Fig. 5. Cells cultured in the synthetic medium with sodium lauryl sulphate as the sole carbon and sulphur sources were washed by centrifugation and varied amounts of cells assayed for activity by methylene blue-sodium dodecyl sulphate complex method. Viable cells (v.c.) were plated in tryptone-agar and counted after two days.

complex method. The bacteria were cultured overnight in a synthetic minimum medium with sodium lauryl sulphate as the sole carbon and sulphur source with vigorous shaking at 36° C. The bacteria were collected by centrifugation and washed twice with 0.14 M sodium chloride. Portions containing varying numbers of collected and washed bacterial cells were mixed with 0.033 mM of dye-detergent complex in 0.05 M *tris*-hydrochloric acid buffer (pH 8) solution containing 0.14 M sodium chloride (*tris* 8.8). The activity of intact cells can be obtained by dividing the rate in the linear part of the curves in Fig. 5 by the number of cells. It can be seen that 30  $\mu$ moles/ml. sodium dodecyl sulphate were split in 60 min with  $1.7 \times 10^7$  bacterial cells per ml., whereas a concentration of  $0.85 \times 10^7$  bacterial cells required 120 min to accomplish the same degree of detergent degradation. The intact cell activity was found to be about 1.8  $\mu$ moles of sodium dodecyl sulphate degraded per  $10^8$  bacterial cells per hour. This rate may also be expressed as  $1.8 \times 10^{-8}$   $\mu$ moles of detergent split per bacterium per hour under conditions of 32° C and pH 8.0.

With the use of the same technique, a series of separate experiments was performed in order to confirm the estimated amount of sodium dodecyl sulphate split per bacterium per hour at a temperature of 32° C and at pH 8. The results are summarized in Table 1. In the experiment of January 20, the same lot of bacteria was used for the comparison of the rate of reaction at 32° C and 22° C. The rate of reaction at 22° C was approximately half that at 32° C. The average activity from four separate experiments was  $1.4 \times 10^{-8}$   $\mu$ moles per cell per hour at a temperature of 32° C and at pH 8.

Table 1. ACTIVITY OF INTACT CELL BY COMPLEX METHOD

Date	O.D.	Viable count	v.c./O.D.	Units/ml.	u./O.D.	$\mu$ moles/v.c./h	React temp.
Jan. 16	7	$6 \times 10^8$	$0.88 \times 10^8$	7.5	1.1	$1.25 \times 10^{-8}$	32° C
Jan. 20	4.5	$5.1 \times 10^8$	$1.1 \times 10^8$	9.0	2.0	$1.7 \times 10^{-8}$	32° C
	4.5	$5.1 \times 10^8$	$1.1 \times 10^8$	3.9	0.9	$0.76 \times 10^{-8}$	22° C
Jan. 23	6.0	$7.8 \times 10^8$	$1.3 \times 10^8$	12.4	2.1	$1.6 \times 10^{-8}$	32° C
Jan. 28	7.5	$11.0 \times 10^8$	$1.5 \times 10^8$	11.4	1.5	$1.0 \times 10^{-8}$	32° C

Average =  $1.4 \times 10^{-8}$   $\mu$ moles/cell/h (at 32° C, pH 8).

Cells grown overnight in the synthetic medium with sodium lauryl sulphate as sole carbon and sulphur source at 36° C were washed and absorbancy measured. The sodium dodecyl sulphate splitting activity was assayed by the complex method with various amounts of viable cells (v.c.). The activity of intact cells was calculated by the method described in the text and with data from Fig. 5.

**Substrate specificity of intact bacteria.** Varying amounts of sodium dodecyl sulphate and sodium dodecyl benzene sulphonate (DBS) were combined in proportions that maintained a constant concentration of total detergent. The mixtures were mixed with constant amounts of the enzyme extracted from the sodium dodecyl sulphate-adapted bacteria. The results of the reaction are shown

Fig. 6. Substrate specificity of intact cells. Varied molar ratios of sodium dodecyl sulphate to sodium dodecyl benzene sulphonate, having equal total concentrations, were mixed with methylene blue and incubated with constant amount of intact cells. The amount of methylene blue released from dye-detergent complex was measured by the complex method.

in Fig. 6. This experiment shows that the sodium dodecyl sulphate splitting enzyme has no effect on dodecyl benzene sulphonate.

It has been stated by several authors<sup>4,6</sup> that the secondary alkyl sulphates are not biologically degradable. In order to ascertain the specificity of the sodium dodecyl sulphate splitting bacteria on the branched secondary alkyl sulphates, further tests were made. It was found that the sodium dodecyl sulphate splitting bacteria could not utilize the branching secondary alkyl sulphate such as the sodium salt of the sulphate of 2-methyl-7-ethyl-4-undecanol ('Tergitol') as the sole carbon and sulphur source. The enzyme extracted from sodium dodecyl sulphate-adapted bacteria was found unable to release methylene blue into the aqueous phase from the complexed branching secondary alkyl sulphate when assayed by the dye-detergent complex method. Attempts to isolate bacteria which can utilize the branched secondary alkyl sulphates as their sole carbon and sulphur sources so far have not been successful.

The foregoing results permitted some interesting calculations. In order to split one part per million (1 mg/l.) or  $3.5 \times 10^{-3}$   $\mu$ moles/ml. of sodium dodecyl sulphate at 32° C in 1 h, it was found that  $2.5 \times 10^8$  cells/ml. of adapted bacteria are required. At a temperature of 22° C or lower,  $5 \times 10^8$  or more cells per ml. would be required.

As reported previously, the sodium dodecyl sulphate splitting enzyme is adaptive, and the enzyme adapted to dodecyl sulphate is also able to split decyl and tetradecyl sulphate. The micro-organisms must be adapted to one of these alkyl sulphates in order to split the detergent. At present there is no way of knowing whether bacteria in Nature are adapted to sodium dodecyl sulphate. The raw sewage sampled at the influent to the Baltimore Back River Sewage Treatment Plant was noted to contain about  $10^3$ - $10^4$  cells per ml. which could potentially utilize sodium dodecyl sulphate both as carbon and sulphur sources. Knowing the number of detergent-splitting bacteria in Nature, temperature, pH and the rate of detergent-splitting activity per bacterium per hour, one will be able to calculate the theoretical maximum load of detergent that can be destroyed completely within a given treatment period.

From the point of view of degradability, the alkyl sulphates are believed to be superior detergents over alkyl benzene sulphonates. The following three reasons support this view: (1) alkyl sulphate splitting bacteria do exist in Nature; (2) the detergency can be destroyed even in an anaerobic condition by hydrolysing the sulphate ester linkage; (3) the rate of splitting alkyl sulphates by bacteria is fairly rapid.

The primary purpose of this article is to suggest that more detailed knowledge can be obtained on the extent of microbial-specific substrate interaction. It is acknowledged, however, that in Nature the derived rates could vary considerably from the figures calculated from laboratory observations. Nevertheless, as factors controlling the reaction are clarified, a greater understanding will be gained with regard to the failures of conventional waste-treatment processes to degrade detergents biologically. Conceivably, there are several factors that could contribute to the present problem. Some of these are: (1) An adequate number of potential organisms may be present in the water system, but these organisms may not be adapted to the detergent. (2) Adapted organisms may exist, but the time provided is insufficient for complete degradation under prevailing temperature conditions. (3) The detergent loading may be in excess of the amount that can be handled by the existing adapted microbial population. (4) There are large numbers of detergent isomers which antagonize each other and cannot be utilized by micro-organisms. (5) Certain synthesized chemical structures cannot be utilized by bacteria.

# MYXOMATOSIS AND THE RABBIT FLEA

By DR. PAUL J. CHAPPLE\* and N. D. LEWIS

Ministry of Agriculture, Fisheries and Food, Infestation Control Laboratory, Worplesdon, Surrey

MUIRHEAD-THOMSON (1954, unpublished) established that the rabbit flea (*Spilopsyllus cuniculi* (Dale)) is the major vector of myxomatosis in Great Britain, but very little work has been done since on the relationship of the virus with the rabbit flea.

In Britain over the past 10 years it has been observed that outbreaks of myxomatosis may occur several months after a previous outbreak in the same locality appears to have ended, although there is no evidence that the virus has been re-introduced. We thought that virus might survive on a few infected fleas which lived-on in a burrow after leaving a myxomatous rabbit. This article describes experiments done to test this idea.

It is impossible to keep rabbit fleas under natural conditions and be sure that they have not had access to a host (either a rabbit or another mammal). We therefore devised the following technique. Fleas were put into 3 in. x 1 in. glass tubes together with some rabbit fur, and the tubes were closed with a special polythene stopper (Fig. 1). These tubes were then put on a metal tray strewn with earth, and placed in an artificial burrow in such a way that individual tubes could be removed without disturbing the others.

Fig. 1

Two experiments on the survival of fleas underground were carried out. Fleas were fed on a rabbit with advanced myxomatosis, and immediately after feeding were put underground. In the first experiment 9 of the special tubes, each containing 10 fleas, were put underground. As a control, 9 completely stoppered tubes without fur were put in the refrigerator at 4° C, as it has been reported (Allan<sup>1</sup>; Rothschild, personal communication) that fleas may be preserved alive for many months in this way.

\* Present address: World Health Organization International Reference Centre for Respiratory Virus Diseases, Common Cold Research Unit, Salisbury, Wilts.

Table 1. SURVIVAL OF FLEAS UNDERGROUND AND AT 4° C

Site of storage	Proportion of fleas still alive when removed after days indicated						
	0	7	14	28	42	56	74
Refrigerator (4° C)	100%	100	90	20	0	0	0
	10/10	10/10	8/10	2/10	0/10	0/10	0/40
Underground	100%	60	100	40	0	0	5
	10/10	6/10	10/10	4/10	0/10	0/10	2/60

Table 1 shows the numbers of fleas surviving in tubes sampled at various times up to 74 days. It can be seen that underground storage preserves the fleas just as well as storage in the refrigerator.

In the second experiment (Table 2) 2 tubes, each containing 25 fleas, were put underground and removed at the end of 84 and 105 days, respectively. There were 5♂ and 2♀ survivors after 84 days and 2♂ and 2♀ survived for 105 days.

Table 2. SURVIVAL OF FLEAS UNDERGROUND

Days underground	No. of fleas examined	♂	No. of fleas alive	Total
84	25	5	2	7
105	25	2	2	4

Having shown that some fleas could survive at least 105 days without feeding, we wished to see whether myxoma virus could also survive. As a preliminary experiment to obtain information on this point, the fleas which had not been put underground or in the refrigerator (that is, the 'time 0' sample of the first experiment) were taken, together with the fleas which had been underground for 74 days. These pools were washed, with the aid of ultrasonics, in tissue culture medium '199' containing 5 per cent calf serum. The fluids were inoculated in 0.1 ml. quantities into marked sites on the shaved back of a healthy rabbit. After about 3 days all the sites showed a specific reaction indicating that virus was associated with some of the fleas. The next experiments were to determine how much virus was to be found on a flea after it had fed on an infected rabbit. A group of 5 fleas that had been allowed to feed on a lesion of a myxomatous rabbit was washed twice in 2.5 ml. tissue culture medium '199' with the aid of ultrasonics. We thought that virus released in this manner represented virus that was on the outside of the flea. The washed fleas were then ground in a pestle and mortar with 1 ml. of medium '199'. The aim in this latter manoeuvre was to try to release virus inside the fleas. The 3 fluids obtained by this technique were titrated using doubling dilutions inoculated in multiple sites on the shaved back of a rabbit. (This is the chessboard technique described by Fenner and Marshall<sup>4</sup>.) Table 3 shows the results obtained.

Table 3. AMOUNT OF VIRUS PRESENT ON FLEAS

Material	Total virus from 5 fleas RID 50*	Average amount of virus/flea RID 50
1st wash with U/S†	80	16
2nd wash with U/S	160	32
Ground-up fleas	1,180	236

\* Rabbit infection dose.

† Ultrasonics.

Fig. 2

We concluded that virus can be removed from fleas by washing and that there is a substantial fraction which can only be released by grinding. The next step was to see whether virus could be detected on all fleas removed from an infected rabbit. Two washings were given to each of 16 fleas, using 0.5 ml. quantities of '199' for each wash. To titrate these samples embryonated hens' eggs were chosen which, although not as sensitive as rabbit skin, were much easier to handle and permitted larger numbers of titrations to be done in a given time. Fig. 2 shows the distribution of numbers of pocks obtained from individual fleas. It can be seen that something like 43 per cent of the fleas examined did not have virus which could be detected by our washing followed by titration in egg technique.

It had now been established that virus was present on infective fleas even after 74 days, and there was some indication of how much virus was associated with an individual flea immediately after contamination. The

next step was to see whether virus, on fleas which had survived long periods of starvation, would be transmitted to healthy rabbits by the fleas biting these hosts. In the second survival experiment (Table 2) it was found that some fleas survived for 84 and 106 days. These survivors were put into glass tubes, and by inversion of the tube on to marked sites on the shaved back of a rabbit it was possible to see whether they fed.

Table 4 shows what happened.

Table 4. NUMBER OF FLEAS INFECTIVE AFTER STORAGE UNDERGROUND

Days	Total	No. of live fleas		Infected a rabbit
		Did not feed	Fed	
84	7	4	3	2
106	4	2	2	1

The significant finding in this experiment was that virus can be preserved on, and transmitted by, such surviving fleas.

The indirect evidence of previous workers on the vectors of myxomatosis is that no multiplication of the virus takes place in the vector. This is certainly true in the mosquitoes transmitting myxomatosis in Australia<sup>1</sup>. Andrewes *et al.*<sup>2</sup> in Britain could not detect multiplication of virus in the mosquito *Anopheles maculipennis atroparvus*, and Muirhead-Thomson (unpublished) found no evidence of multiplication of virus in rabbit or squirrel fleas. We are therefore left to conclude that the quite small amount of virus found on the rabbit flea is in a very stable form, probably protected by extraneous protein derived from the myxomatous lesion.

From our experiments we conclude that fleas can survive for very long periods without feeding and that the virus associated with the fleas can be removed by washing them with the aid of ultrasonics or by grinding them up. Virus acquired by feeding on infected rabbits can also survive on the fleas so that they are infective for healthy rabbits.

## INTERACTIONS IN THE SYSTEM GALENA – POTASSIUM ETHYL XANTHATE – OXYGEN

By PROF. A. M. GAUDIN

Department of Mineral Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts

AND

DR. N. P. FINKELSTEIN

Government Metallurgical Laboratory, Johannesburg, South Africa

PROMPTED by the commercial importance of the flotation process in the recovery of sulphide minerals, numerous investigations have been carried out on the interaction between these minerals and the reagents used, particularly xanthates. Plaksin *et al.*<sup>1</sup> have developed the idea that oxygen plays an important part in the reaction, and this is clearly and strongly supported by the infra-red spectrophotometric studies of Leja and Poling<sup>2,3</sup>. However, the part which oxygen plays is by no means fully understood. Knowledge of the subject at the present time is entirely qualitative, and, indeed, even the fact of the essential nature of the action of oxygen is not universally accepted. Recent publications<sup>4,5</sup> suggest that some adsorption of xanthate takes place on galena even when elaborate precautions are taken to reduce the oxygen content of the system.

We have initiated an intensive programme of research work, aimed at resolving the conflict and providing a quantitative description of the interaction between xanthate, oxygen, and sulphide minerals. The present report describes the results of a preliminary investigation using galena and potassium ethyl xanthate.

The flowing reaction apparatus used was constructed entirely from glass and 'Teflon', and enabled deoxygenated solutions of different reagents to be passed successively through a bed of galena without being exposed to contamination from the atmosphere. The abstraction of xanthate from the solution during its passage through the bed was determined by a spectrophotometric analysis of the effluent. The galena used was prepared from pure lumps of natural galena, and had a specific surface of approximately 350 cm<sup>2</sup>/g. Xanthate solutions were used at

Fig. 1. The effect of additions of oxygen on the xanthate concentration in the effluent solutions from a bed of galena. *a*, No oxygen added; *b*, 0.6 p.p.m. oxygen added to xanthate solution only; *c*, oxygen added to both rinse and xanthate solutions in concentrations of (i) 0.8 p.p.m., (ii) 6.4 p.p.m.

a concentration of  $3.2 \times 10^{-4}$  M and pH 8, and were prepared from repeatedly recrystallized potassium ethyl xanthate.

From the outset, results that differed markedly from those of previous investigators<sup>4,5</sup> were obtained. Those investigators had reported an initially low xanthate concentration in the effluent solution, which increased with throughput until it became equal to the influent concentration; and they had interpreted this as indicating an adsorption of xanthate by the mineral, at first rapid, but then slowing, until finally it ceased. We found that the effluent concentration remained significantly different from that of the head solution for as long as the flow of solution was continued (up to several days), though the cumulative loss of xanthate was equivalent to many hypothetical adsorption monolayers. Furthermore, the effluent concentration was markedly sensitive to the flow-rate of the solution, which suggested that the difference might be due to our use of low flow-rates (0.3–1.5 ml./min).

We learned from Dr. O. Mellgren<sup>6</sup> that considerably higher flow-rates (100–200 ml./min) had in fact been used during his work. This difference in the flow-rates is equivalent to a two-hundred-fold difference in the residence time and hence in the sensitivity of detection of reaction. When our procedure was modified so as to bring the residence time more in line with that obtaining in Mellgren's work, we were able to reproduce quite closely the behaviour that he reported.

We proceeded to examine in greater detail the unexpected phenomenon of the continuing abstraction of xanthate from solution by galena. The introduction of an upward-flow column with its more mobile bed did not eliminate the effect; thus it disposed of the possibility that it might be associated with a mechanical occlusion of part of the mineral surface. Similarly, little improvement resulted when the mineral was pretreated with dithionite, and chemical deoxidants (sodium hypophosphite, sodium phosphite) were dissolved in the rinse and xanthate solutions. The behaviour of the system was significantly changed only when the following procedure for the exclusion of oxygen was adopted. The mineral sample was pretreated with a sodium sulphide solution at a pH between 8 and 9 and then rinsed with water that had been deoxygenated by the passage of nitrogen for several hours. The xanthate solution used had also been thoroughly deoxygenated in the same way. This expedient was effective in reducing the long-term interaction to a rate well below the minimum detectable in the apparatus, namely,  $10^{-6}$  mole  $\text{cm}^{-2} \text{sec}^{-1}$ , and the total detectable long-term abstraction of xanthate to the order of 1 per cent of a hypothetical absorbed monolayer, a level which is also of the same order as the experimental limit. The observations show that no interaction takes place between galena and xanthate solutions in the absence of oxygen. This conclusion is in complete agreement with the findings of Leja and Poling<sup>7,8</sup>.

With the establishment of an effective technique of deoxygenating the system, we were in a position to begin investigating the effect of controlled additions of oxygen. In some experiments these were made to both the rinse and xanthate solutions, but in others, to the xanthate solution alone. The major features of the behaviour observed are illustrated in Fig. 1. In all instances, the

Fig. 2. Relationship between the quantity of xanthate abstracted from solution,  $A$ , and the time of contact with galena,  $t$ . *a*, 0.6 p.p.m. oxygen in xanthate solution only; *b*, 0.8 p.p.m. oxygen in both rinse and xanthate solutions; *c*, 6.4 p.p.m. oxygen in both rinse and xanthate solutions.

system eventually settled down to a continuing abstraction of xanthate from solution at a finite rate, which decreased slowly with time but did not become constant within the period of the experiment. The behaviour in the initial stages of the experiments depended on the oxygenation procedure. When the addition of oxygen was restricted to the xanthate solution, no strong interaction occurred until the mineral and the solution had been in contact for some time (compare Figs. 1a and b). On the other hand, when both the rinse and xanthate solutions contained oxygen, the abstraction of xanthate began immediately the solution was placed in contact with the mineral (Fig. 1c). However, as the elution curves show a distinct maximum in the initial stages, it appears that an induction period is still required before the reaction attains its full rate.

Fig. 2 shows typical graphs obtained by plotting  $A$ , the total quantity abstracted from solution, against the logarithm of  $t$ , the time for which the solution has been in contact with the mineral. After an initial period, during which the slope of the plot of  $A$  versus  $\log t$  increases steadily, the system obeys an equation of the form:

$$A = D \ln t + C \quad (1)$$

where  $C$  and  $D$  are constants. The abstraction value equivalent to a hypothetical adsorbed monolayer is indicated in the figure, as are the times at which changes were made in the solution flow-rates. No change in the behaviour of the system is apparent at these points. The curves are influenced by oxygen concentration; but the relationships are not simple, and it is thought that a more precise control of the oxygen concentration will be necessary before they can be quantitatively defined.

Equation (1) is of the same form as the direct logarithmic equation<sup>7</sup> that has been used to describe the rate of growth

of oxide films in the low-temperature corrosion of metals. It may be reduced to:

$$dA/dt = D \exp(C-A)/D \quad (2)$$

which is of the same form as the Elovich equation<sup>8</sup>, which was developed to describe the chemisorption behaviour of gases on semiconductors. The similarity between the reaction kinetics of metallic and semiconductor surfaces with gaseous reagents and with dissolved reagents is of considerable interest. It suggests that there is a common rate-limiting mechanism that is dependent on the properties of the surface. Both the empirical equations referred to have been justified theoretically<sup>9,10</sup> by assuming a surface-energy barrier in which the rate-limiting step is the transfer of an electron between the adsorbant and the adsorbate.

Continuing research on this topic is aimed at confirming these indications on the mechanism of the interaction and quantitatively determining the effect of oxygen.

This work was performed during the tenure by one of us (N. P. F.) of an appointment as visiting scientist at the Massachusetts Institute of Technology, sponsored by the Government Metallurgical Laboratory, Johannesburg.

## A COMPUTER PROGRAMME FOR PLOTTING A CRYSTALLOGRAPHIC FOURIER SYNTHESIS

By PAUL CHERIN

Fundamental Research Laboratory, Xerox Corporation, Webster, New York

R. MADIGEN

IBM Corporation, Huntsville, Alabama

AND

T. MARTIN

Stevens Institute of Technology, Hoboken, New Jersey

A PROGRAMME known as plot crystallographic (which will be designated as PC) has been written for the purpose of plotting the results of a Patterson section or a two-dimensional summation, three-dimensional section or a two-dimensional crystallographic Fourier synthesis on the IBM 7090 Data Processing System and the X-Y plotter of the Electronic Associates, Inc., analogue computer. In addition, the positions of the maxima are determined by a parabolic interpolation by the method of Booth<sup>1</sup>.

In view of the availability of computing time and of efficient programmes, it is no longer necessary to do Fourier summations manually. It would also seem advantageous to circumvent the tedious plotting operation by utilising programmes such as PC. There are many similar programmes where the results can be observed on the screen of an oscilloscope, but it is convenient to have the results printed directly on a chart with both the contours

and maxima clearly marked. In addition, PC is suitable for non-orthogonal projections.

This programme has been written in Fortran for the IBM 7090. It can be combined with a programme for carrying out a Fourier synthesis. The results of the Fourier summation are read into the memory directly from the tape. The PC programme examines the array positions in the memory and locates a set of contours of equal electron density and positions of the maxima and plots them on a chart.

The chart may be divided into several parts by a sub-routine; as many as eight Fourier summations can be plotted on one surface. After the chart has been divided, the X-Y plotter is instructed to draw the axes of the unit cell by plotting  $x = 0$ ,  $y = 0$ , if the unit cell is orthogonal. Any other line can be drawn just as easily. The plotter places points along lines representing the axes. These points are separated by a space representing

1/60 of the unit cell edge (or whatever fraction is chosen). The spacing between the points is proportional to the length of the axes, so each co-ordinate of the unit cell is represented by a specific position on the chart.

The computer is directed to plot specific contours. Adjacent positions in the memory are examined for any included contour line. If such a line is found, a linear interpolation is carried out in order to determine its exact location.

If the axes are not orthogonal, the array of contours must be transformed into its natural configuration. If the projection of the two-dimensional Fourier summation is on to the  $x$ - $y$  plane and the angle between  $a$  and  $b$  axes of the unit cell is  $\gamma$ , the new co-ordinates can be defined in terms of the old by means of the relationships:

$$\begin{aligned} x' &= y \cos \gamma + x \\ y' &= y \sin \gamma \end{aligned} \quad (1)$$

The co-ordinates of each contour point are translated into meaningful information for the analogue X-Y plotter. This information is recorded on tape by a sub-routine. Each row of the array is examined in this manner, and the entire process is carried out again on the columns.

The calculated array is then re-examined to find the maximum value of electron density within the contours. The rows are scanned until a specified contour line is encountered. The positions within the contour line are examined. The array position of maximum electron density is determined using a modified version of Booth's method of parabolic interpolation.

Fig. 1. The general case of a contour and the position of maximum electron density within it

Fig. 2. Electron density of  $\text{NaNO}_3$ , showing the shape and position of the maximum representing the oxygen atoms

Fig. 1 shows the general case of a contour and the position of maximum electron density within it. When the projection is on to a non-orthogonal plane, Fig. 1 (top) is transformed into the figure shown in Fig. 1 (bottom).

The point  $T(x,y)$  is the array position on the tape having the maximum electron density within the contour.  $P$  and  $Q$  are the positions of maximum density along the lines  $x'$  and  $y'$ , respectively. The co-ordinates of  $C$  relative to  $T(x,y)$  can be found by means of equations (2) and (3). Utilizing Fig. 1 (top) and a parabolic interpolation, it can be shown:

$$P = \frac{\rho(x-1,y) - \rho(x+1,y)}{2[\rho(x-1,y) + \rho(x+1,y) - 2\rho(x,y)]} \quad (2)$$

where  $\rho(x,y)$  is the magnitude of the electron density at  $(x,y)$ .  $Q$  can be determined in a similar manner. The position of  $C(x',y')$  can be determined from equation (3):

$$\begin{aligned} C(x) &= P(x) \\ C(y) &= Q(y) \end{aligned} \quad (3)$$

When the unit cell is not orthogonal (Fig. 1, bottom), the position of the maximum must be transformed according to equation (1).

The co-ordinates of the maximum can now be determined with respect to the origin.

$$X'_{\text{max}} = C(x') + T(x') \quad (4)$$

$$Y'_{\text{max}} = C(y') + T(y') \quad (5)$$

The calculated values of  $X'_{\text{max}}$  and  $Y'_{\text{max}}$  are stored on tape to be plotted with the contours. All the elements within the original contour line are set equal to zero so that this maximum will not be encountered again. Scanning by rows is continued until the entire array has been examined.

The result of such a plot is shown in Fig. 2. Each point represents a specifically chosen electron density which is included between two array positions in the memory. Their locations have been determined, stored on tape and plotted. The outermost contour represents  $5 \text{ e}\text{\AA}^{-3}$ . Each inner contour increases by 5 units until the maximum of  $25 \text{ e}\text{\AA}^{-3}$  is reached. Fig. 2 is an illustration of an electron density difference map showing only the oxygen atoms in  $\text{NaNO}_3$ . This section is parallel to the "ac" plane of the hexagonal unit cell. The maxima represent the distribution of the oxygen atoms about a six-fold axis. Hence, the maxima are all of the same magnitude.

The programme is described in more detail in ref. 2.

## ASTRONOMY

### Barred Spirals and Formation of Spiral Arms by Galaxies

So far the formation of spiral arms, especially regular arms, has not been satisfactorily explained. The investigation of this phenomenon can be facilitated by an analysis of similar, but more peculiar, objects—barred spirals. A characteristic barred galaxy has a straight bar, which at the ends transforms abruptly into spiral arms. The population of bars and arms belongs to type I. For the bar to rotate and conserve its straight-line form it is necessary that the gravitational field within the limits of the bar corresponds to solid body rotation, as, for example, inside a homogeneous sphere. Beyond the ends of the bar rotation is differential, that is, the density should decrease sharply with distance. The density distribution is not determined by the bar but by the old stars of low luminosity. Consequently the old stars in an SB should form either a homogeneous sphere or a disk with a very small concentration toward the centre of the galaxy and their density should suddenly decrease at some distance.

Ordinary spirals and SB were formed during the condensation of gas clouds. For some reason in SB the gas, which had not as yet transformed into stars, was removed to some distance. A sharp boundary can be produced only by a shock wave. It is assumed that powerful explosions, similar to that observed in *M* 82, occurred very frequently at an early stage of evolution of galaxies. Such an explosion sweeps the gas from the central region and concentrates it into a thin spherical shell, the motion of which is retarded by gravitation. If the energy of the explosion exceeds  $10^{47}$ – $10^{48}$  ergs, a shell with  $M \approx 3 \cdot 10^{10} M_{\odot}$  and  $R \approx 10$  kiloparsecs can be formed. If the gas of a galaxy had time to form a flat disk before the explosion, the latter throws out some of the mass along the minor axis. However, its influence on mass distribution in the disk should not be of great importance. Therefore it is assumed that the explosion occurred in a spherical protogalaxy, that is, at the stage of formation of stars of the spherical sub-system. A thin gas shell ( $\Delta R \approx 0.1 R$ ) with  $R = 10$  kiloparsecs can exist for about  $5 \times 10^7$  years. In this time the temperature of the gas should decrease to  $T \leq 5000^{\circ}$ , which is sufficient for fragmentation as the density in the shell is about  $3 \times 10^{-24}$  g cm $^{-3}$ . Clusters and stars with a relatively low angular momentum and high energy are formed. They move along elongated trajectories, and their spatial density is approximately uniform, increasing toward the centre and periphery of the sphere. The concentration toward the centre depends on the angular momentum distribution. The density distribution at the distribution of momentum observed in our Galaxy is given in Fig. 1. The angular velocity  $\omega(r)$  differs only slightly from  $\omega_0$ —the angular velocity at the edge of the sphere.

A constant  $\omega$  is necessary but not sufficient for the straight-line form of the bar. First of all,  $\omega$  is not exactly a constant; secondly, the break at the ends of the bar should be smoothed rapidly by the tension of the lines of force of the spiral arms. Therefore, it is necessary to assume that there are clusters of old stars with  $M \geq 10^6 M_{\odot}$  at the ends of the bar. Inside each cluster there is a gas cloud with  $M \geq 10^6 M_{\odot}$ . At such values the

magnetic forces cannot drag the gas out of the clusters and the deceleration of clusters during  $10^{10}$  years is not very essential. The tension of the magnetic lines between the clusters and the centre straightens the bar and forces it to rotate with a constant angular velocity  $\omega_0$ . The difference  $\omega - \omega_0$  accelerates the gas to the ends of the bar with a velocity of 20–30 km/sec and in the central region moves it toward the centre. Motion to the edge is observed spectroscopically and motion toward the centre explains the presence of gas and hot stars which are usually absent in the centres of ordinary spiral galaxies.

The formation of a bar can be assumed as follows. The gas of the shell, which did not develop into stars, loses energy and forms a disk with circular orbits. The fraction of gas with a low angular momentum concentrates toward the centre together with the tube of magnetic lines frozen in the gas (Fig. 2). The magnetic forces in such an over-tight tube tend to compress the neighbouring parts of the tube. These forces are small in comparison with the gravitational forces and the pressure gradient. However, they serve as small perturbations which develop due to gravitational instability. A condensation is formed at each side of the central thickening and the process is repeated, the magnetic forces stimulating the condensation of gas along the magnetic tube. A magneto-gravitational wave propagates along the magnetic field. Its propagation is facilitated by the general instability of the gas disk. Deviation from axial symmetry leads to the condensation of gas at several radii. The process of condensation of the tube occurs simultaneously with the

Fig. 1 —  $\omega(r)/\omega_0$ ; ---  $\omega^2(r)/\omega_0^2$

Fig. 2

flattening of the disk. When the wave reaches the remnants of the shell, clusters are formed at the ends of the bar and later spiral arms. The mechanism of formation of ordinary spirals is also connected with the central condensation from which the magneto-gravitational wave originates. Condensation ceases when the magnetic forces, which increase more rapidly than other forces, balance gravitation. The connexion between the central condensation and spiral arms explains the fact that irregular galaxies, which have no central condensation, do not have spiral arms.

SB galaxies often have a ring, the diameter of which is a bar. Besides this ring there are spiral arms extending from the ends of the bar and tangential to the ring. This ring is probably a remnant of the shell, which condensed to the galactic plane. The fraction of gas with a comparatively large angular momentum could, during contraction in the shell and subsequent condensation to a plane, become a gravitationally stable ring, similar to a spiral arm.

The magnetic lines of force extending from the semi-rings and bars are prolonged in the spiral arms. At the places of exit they are compressed by the gas clouds of the clusters (Fig. 3). The splitting of spiral arms into several looks, often observed in ordinary galaxies, is naturally explained: gravitational condensation, which was induced by a single magneto-gravitational wave, could have resulted in the formation of several separate masses, from which separate magneto-gravitational waves originated.

Fig. 3

The relatively high percentage of SB and the short duration of the contraction phase of the spherical subsystem of a galaxy show that the occurrence of powerful explosions was very probable at this phase. Consequently the development of superstars depends on the amount of gas with a low momentum in a galaxy, that is, it is apparently connected with the condensation of massive gas clouds.

The magneto-gravitational wave can explain the bridges and tails of interacting galaxies. The condensation of a galaxy in a large gas cloud facilitates the condensation of the gas along the lines of force of the metagalactic field. When the wave reaches a denser part of a cloud, a second galaxy is formed. The wave propagates further if gas in a state close to gravitational instability is present.

So far the spiral arms have been considered as tubes of parallel magnetic lines. However, if the angle between the magnetic field and the axis of rotation is acute, spherical contraction and subsequent flattening of the gas lead

Fig. 4

to a field given in Fig. 4. This explains a recently detected fact: the rotation of the polarization plane of radio sources shows that in the solar vicinity at both sides of the galactic plane the field is of opposite sign. In accordance with Fig. 4 the rotation measured in these two semi-spheres is not equal. In the vicinity of the neutral line the field becomes annihilated and magnetic pressure does not support the gas. Probably here interstellar clouds and associations are formed.

## ASTROPHYSICS

### Globular Clusters as Remnants of Quasars

In the past two years many theories have been advanced for the explanation of the extraordinarily powerfully emitting cosmic energy sources known as quasistellar radio-sources, or quasars for short. Two particular theories have been brought out in an especially detailed form, namely, the gravitational collapse theory of Hoyle and Fowler<sup>1</sup> and the spherical galaxy formation theory of Field<sup>2</sup>.

It is the purpose of this communication to direct attention to a class of objects, the globular clusters, that may provide tangible evidence for quasar events in the past history of our Galaxy. If this connexion is proved to be true, astronomers will have a unique opportunity of investigating the stellar remnants of actual quasar cores.

Here is outlined qualitatively a model for the formation of globular clusters which draws on some conceptual elements and results from the foregoing two theories, and at the same time some of the consequences of such a model for the explanation of quasar characteristics are discussed.

We identify the supermassive objects of Hoyle and Fowler ( $M/M_\odot = 10^4$ – $10^6$ ) with proto globular clusters, that is, nascent globular clusters. According to the best estimates at present<sup>3</sup> the masses of globular clusters range from roughly  $10^5$  to  $10^7$  solar masses, and it is reasonable to assume that those of the proto globulars are somewhat larger. Representative globular cluster sizes are of the order of 10 parsecs, which incidentally is the estimated lower limit to the size of the HII region of the core of the quasar 3C48, investigated by Greenstein and Schmidt<sup>4</sup>.

I propose that the evolution of the proto globular cluster proceeds along the lines of Hoyle and Fowler's supermassive objects up to the onset of nuclear burning. However, the time for free-fall collapse is so short ( $7.5 \times 10^4$  years for  $M = 10^4 M_\odot$  and 25 years for  $M = 10^6 M_\odot$ , (ref. 5)) and the central temperatures in the later phases of contraction become so high ( $\sim 10^8$  °K) that we are led to postulate the occurrence of the Alpher, Bethe, Gamow non-equilibrium theory of element formation ( $(\alpha, \beta, \gamma)$ -process)<sup>6</sup>. This implies that significant element formation beyond helium does not take place in the proto globular cluster, if the initial material is pure hydrogen.

We then adopt the results of Michel<sup>7</sup> regarding the collapse of the massive star after the exhaustion of nuclear energy. In this theory, the central core ( $M_c = 0.3 M$ ) will collapse much more rapidly than the outer envelope and this results in a separation of the two parts. The suggestion of Hoyle and Fowler is followed that a significant amount of energy is transferred from the core to the envelope, which leads to a rapid expansion of the envelope away from the imploding core. This expansion phase is analogous to the situation envisaged by Field in his 'rebound'-phase. However, Field assumes star-formation to take place before the 'rebound', but we prefer to place

this event after the 'rebound' and to assume that the ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-process of element formation takes place before maximum compression of the envelope. Incidentally the density,  $10^{-10}$  g/cm<sup>3</sup>, for which Field finds a maximum rate of star formation, is equivalent to the smeared-out density of a globular cluster with radius 10 parsecs and a mass of  $10^7$  solar masses.

The reason for my choice of sequence of events rests on the observed element characteristics of the halo globular clusters with their well-documented metal deficiencies. In particular the results of O'Dell, Peimbert and Kinman<sup>8</sup> show that in the halo globular cluster M15 the helium to hydrogen ratio is  $0.18 \pm 0.03$ , while the ( $\alpha$ ,  $\beta$ ,  $\gamma$ ) non-equilibrium value is 0.15. The inference of the operation of the ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-process in proto globular clusters is further strengthened by the fact that the same authors find M15 strongly deficient in oxygen (1/81 of the solar value). Accordingly, I propose that the ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-burning phase of a proto globular cluster represents a quasar or a quasar element.

A common origin in time for the halo globular clusters in our Galaxy is suggestive in viewing their general metal deficiency and comparable old age. Eggen, Lynden-Bell and Sandage<sup>9</sup> from an analysis of the space motions of 221 dwarf stars infer that some  $10^{10}$  years ago a collapse of a spherical gas mass took place rapidly in a time of about  $10^6$  years. This can be identified as the major quasar event in the history of our Galaxy. Thus I propose that the most energetic quasar events represent a stage of multitudinous globular cluster formation very early in the life-time of a galaxy. The distribution of globular clusters in our own Galaxy and nearby ones like M87, NGC4636, NGC4278, etc., indicates an initially spherical mass distribution which is a major requirement for identification with the spherical starlike photographic images of quasars. I postulate that this spherical mass during its collapse will fragment into proto globular clusters, possibly according to Hoyle's hierarchical fragmentation theory<sup>10</sup>.

The energy source of the quasars then resides principally in the nuclear burning of hydrogen into helium, eventually with gravitational energy added by the final implosion of the quasar core. The mass conversion of 0.15  $M$  of hydrogen into helium in the ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-process leads to an energy release of the order of  $10^{48}$  Mev. If subsequent nuclear burning did take place, this would only add  $3 \times 10^{-4}$  Mev to the energy release. With a mass for the proto globular cluster of  $10^7$ – $10^8$  solar masses this yields an energy release of some  $10^{48}$ – $10^{49}$  ergs. The estimated total energy output for a representative quasar is about  $10^{46}$  ergs/sec. Thus the nuclear fuel content in a proto globular cluster lasts some  $10^5$ – $10^6$  years, which is commensurable with estimated life-times for quasars<sup>11,12</sup>.

It appears that the gravitational energy source is not strictly required even for the explanation of the more energetic quasar events, since in our model we admit the co-existence of several supermassive objects. The number of globular clusters in a given galaxy varies widely from possibly none to about one thousand in the giant elliptical galaxy M87 (ref. 13). In our own Galaxy more than 100 globular clusters have been catalogued, but estimates run to a total of 500 (Allen *loc. cit.*, p. 265). This implies that the energy storage requirement of  $10^{46}$  ergs found by Maltby, Matthews and Moffet<sup>14</sup> for some radio sources can be met by the nuclear energy content available in the limit of  $10^2$  globular clusters of mass  $10^6 M_\odot$ . Such energetic sources should be relatively rare occurrences, restricted to giant galaxies like M87.

If a limited number of globular clusters are formed at approximately but not exactly the same time, the observed light variations in quasars over short periods of time may be readily explained (2–10 years for 3C2 and 3C273 respectively). These light variations would merely be a consequence of the implosion of another proto globular cluster with its onset of an ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-process or the termina-

tion of one. Secondary light effects could reside in subsequent star formation and/or supernovae displays.

The globular clusters in our Galaxy show a spread in age from roughly  $10^8$  to  $10^{10}$  years accompanied by a variation in metal content<sup>15</sup>. This may indicate that after the initial massive quasar event involving the formation of a major number of globular clusters, subsequent milder quasar events, that is, the formations of individual or small groups of globular clusters, can occur. The repetitive quality of quasar events has been suggested on other grounds by, for example, Hoyle and Fowler<sup>16</sup> and also by Shklovsky<sup>17</sup>. As a consequence of our model the ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-process will then operate on gradually enriched material, partly from heavy element creation in stellar interiors and partly from previous hydrogen conversion in earlier ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-processings. The metal richer globular clusters should thus also be richer in helium and eventually become hydrogen-deficient. After ten repetitive ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-processings the helium to hydrogen ratio becomes 0.81 if 15 per cent of the remaining hydrogen is always converted into helium and with no helium further processed.

The youngest globular clusters in our Galaxy are about  $10^8$  years old. If we take this as representative of the most recent state of quasar events in our own and neighbouring galaxies, we should have to go out to spatial distances of  $10^8$  light years in order at present to witness quasar events. As we travel further out in space and back in time, the frequency and possibly intensity of quasar events should increase, particularly at distances of about  $10^{10}$  light years away or events  $10^{10}$  years ago, when presumably the most massive quasar event took place in our own Galaxy. Possibly such a time-space-dependent frequency and intensity variation in quasar events could serve as a cosmological discriminant. At present it is inferred, from the red shifts of quasars, that they occur at great distances, invariably farther out than  $10^8$  light years. The nearest quasar, 3C273, is  $1.55 \times 10^8$  light years away according to estimates by Greenstein and Schmidt<sup>18</sup>.

Finally, I wish to reiterate the unique opportunity that our galactic globular clusters afford in the study of quasar remnants. If the present model or some modification thereof holds true, the centre of a globular cluster will contain an imploded quasar core, which represents a significant fraction of the original mass in 'hidden form'<sup>19</sup>. This should affect the stellar spatial and velocity distributions within the globular cluster.

Likewise I wish to emphasize the importance of studying the hydrogen to helium ratio through possible discoveries of planetary nebulae in globular clusters of differing age. The observed hydrogen to helium ratio will have a decisive bearing on whether or not the ( $\alpha$ ,  $\beta$ ,  $\gamma$ )-process has repeatedly taken place in the material of the proto globular clusters.

## A Search for Low-energy Gamma-rays from the Quasar 3C286

In two experiments on the *Ranger* spacecraft, Metzger *et al.*<sup>1</sup> have observed a flux of low-energy  $\gamma$ -rays at great distances from the Earth. Previous experiments on high-altitude balloons<sup>2,3</sup> and on rockets<sup>4</sup> had looked for, but failed to detect, an isotropic flux of  $\gamma$ -rays incident on the top of the Earth's atmosphere. These experiments used counters with little or no directional sensitivity, and their failure was due to the difficulty in distinguishing between an isotropic primary flux from the background of secondary  $\gamma$ -rays produced by cosmic rays in the atmosphere and in the apparatus itself. However, even in the presence of this background, a counter with directional sensitivity can detect  $\gamma$ -rays from point sources by measuring increases in the total flux in particular directions in the sky. We report here the results of observations made at balloon altitude on the quasar 3C286.

The detector used in this experiment was a 2-in. diam.  $\times$  2-in. high sodium iodide scintillation crystal; it was surrounded by a collimator with an opening angle of  $\pm 5^\circ$ . The telescope was carried to an altitude of 100,000 ft. by balloon on October 28, 1964. During the flight the attitude of the telescope was controlled from the ground by radio-command. Pulse height spectra were recorded from the direction of 3C286 and from neighbouring directions; the spectra were taken frequently, and alternately from the source and from the background, to avoid systematic errors due to changes in the overall gain of the system. A caesium-137 source was carried on the telescope to provide a calibration during the flight. The energy resolution was  $\sim 0.5$  MeV.

The combined spectrum recorded from the direction of 3C286, with the background subtracted, is shown in Fig. 1. The spectrum is not significantly different from zero at any energy.

This result sets upper limits to the flux of  $\gamma$ -rays from several possible processes on 3C286. In each case, the 95 per cent confidence limit is given. No allowance has been made for a possible red-shift of 3C286; the results may need recalculating when the red-shift is eventually measured, but the changes in the limits will probably be small.

(1) *Electron-positron annihilation.* The limit to the flux of 0.51-MeV  $\gamma$ -rays is 0.04 photons/cm<sup>2</sup> sec at the top of the atmosphere.

(2) *Neutron capture in hydrogen.* The limit to the flux of 2.2-MeV  $\gamma$ -rays is 0.13 photons/cm<sup>2</sup> sec.

(3) *Interaction of high-energy electrons with optical photons through the inverse Compton effect.* Ginzburg *et al.*<sup>5</sup> have considered this process for the quasar 3C273, the distance of which is already known. They have

Fig. 1. Pulse height spectrum received from the direction of 3C286 with the background from neighbouring directions subtracted. Errors equal to one standard deviation are shown for each point.

shown that if the optical continuum is due to the synchrotron radiation of high-energy electrons, then the same electrons should produce low-energy  $\gamma$ -rays in collisions with optical photons. If the optical radiation has a spectrum of the form:

$$I(\nu)d\nu = I_0\nu^{-\alpha+1}d\nu$$

then the  $\gamma$ -ray spectrum has the form:

$$F(E)dE = F_0E^{-\alpha}dE$$

The optical spectrum from 3C286 is flat<sup>6</sup>, so the  $\gamma$ -ray spectrum should have  $\alpha = 1$ . The experiment described here sets a limit to  $F_0$  of  $5.5 \times 10^{-8}$  photons/cm<sup>2</sup> sec.

The results of Metzger *et al.* indicate a primary flux with a spectrum of the form:

$$N(E)dE = N_0E^{-1}dE$$

The flux at 1 MeV, integrated over all directions in space, is  $4 \times 10^{-1}$  photons/cm<sup>2</sup> sec MeV. If a similarly shaped spectrum is being emitted by 3C286 the present experiment shows that the limit to the flux at 1 MeV is  $3.6 \times 10^{-4}$  photons/cm<sup>2</sup> sec MeV.

We thank Prof. C. F. Powell for the hospitality of his laboratory. We also thank many members of the laboratory for their assistance, especially Dr. K. G. Standing (now at the University of Manitoba), who initiated the experiment, and Mr. J. H. Davies, who organized the balloon flight.

The telemetry system was designed and built at the Atomic Weapons Research Establishment, Aldermaston. One of us (D. J. A.) thanks the Department of Scientific and Industrial Research for a maintenance grant.

## GEOPHYSICS

### Continental Drift and the Rotation of Spain

SIR EDWARD BULLARD *et al.*<sup>1</sup> have used a 'least squares' criterion for the geometrical fit of the continents around the Atlantic Ocean. They find that the best fits are obtained when the 500-fathom submarine contours are used to define the continental margins. When all the continents are fitted, it is found on fitting Africa to eastern North America that Africa overlaps the position of southern Spain. To avoid this, Bullard *et al.* rotate Spain, closing up the Bay of Biscay as previously suggested for other reasons by du Toit<sup>2</sup> and Carey<sup>3</sup>. The appropriate part of the computer fit is shown in Fig. 1. It is clearly desirable to look for some independent evidence for the rotation of Spain.

Irving<sup>4</sup> has noted that there is some palaeomagnetic evidence for such a rotation. The argument is that the declinations of the directions of remanent magnetization for rocks of Permian and Triassic ages from Spain are different from those of rocks of the same ages from France, Germany, Britain, Norway and the U.S.S.R. The latter are all consistent, indicating that these regions all formed one unit. With the aid of some new results from the northern Pyrenees, this argument is followed up and the palaeo-declinations for rocks from the north and south of the Pyrenees are compared and then related to the bathymetry of the Bay of Biscay.

Measurements<sup>1</sup> of natural remanent magnetization have been made on some volcanic rocks of late Triassic and early Jurassic ages from southern France. These rocks outcrop in the northern foothills of the Pyrenees in a region extending for about 30 km near latitude  $43^{\circ}$  N., longitude  $1.5^{\circ}$  E. The Upper Triassic rocks are mainly quartz basalts and the lower Jurassic rocks include basalts, tholeiitic basalts and various tuffs. All dip steeply northerly. Eighty orientated samples were measured and unstable components of magnetization removed using alternating fields. After applications of geological corrections the Jurassic rocks have mean declination N.  $16.3^{\circ}$  E. (from means of 8 sites) and the Triassic rocks have mean declination N.  $29.2^{\circ}$  E. (from means of 7 sites).

It is of interest to look at these results in relation to the problem of the rotation of Spain. Fig. 2 shows all the palaeomagnetic results for rocks of Permian, Triassic, and Jurassic ages for Spain, France and the southern part of England which are available at the present time. Some interesting features are noted: first, the declinations (disregarding reversals) for Permian, Triassic and Lower Jurassic rocks from southern England and France are remarkably consistent; secondly, the consistency applies to  $T_1$  and  $J_1$  even though these are close to the Pyrenees; thirdly, the declinations for Permian and Triassic rocks from Spain are different from those from France and England.

In view of the consistency of the declinations, it seems reasonable to take the mean declination for rocks to the north of the Pyrenees and compare it with the mean declination for rocks from the south of the Pyrenees (Table 1). In doing this, one result,  $T_1$ , is omitted as it is considered suspect by the original author<sup>14</sup>. In Table 1, all the declinations are written in the northerly sense, that is, disregarding reversals. The mean declination for rocks from the north of the Pyrenees is found to be N.  $20^{\circ} \pm 7^{\circ}$  and the mean declination for rocks from the south of the Pyrenees is found to be N.  $34.2^{\circ} \pm 9^{\circ}$ . The difference is therefore  $38^{\circ} \pm 16^{\circ}$ .

Calculation of the difference from the vector means gives a value of  $40^{\circ}$ . The remanent vectors together with the vector means are shown on an equal-area projection in the inset to Fig. 2.

The difference may be explained by assuming a rotation of Spain, and the values are remarkably close to the rotation of  $39^{\circ}$  obtained from Carey's reconstruction. However, the closeness of these estimates seems fortuitous as measurements on the opening of the Bay of Biscay using the hydrographic charts suggest the rotation might be as small as  $30^{\circ}$  or as large as  $40^{\circ}$ . The computer fit of Bullard gives a rotation of  $32^{\circ}$ . All these estimates are within the experimental error of the palaeomagnetic results and it is considered that the available palaeomagnetic data lends considerable support to the rotation of Spain and the computer fit of the continents as proposed by Bullard.

Fig. 1. The fit of the continents of the Atlantic after Bullard *et al.*, 1965. Spain has to be rotated clockwise  $32^{\circ}$  to obtain the best fit

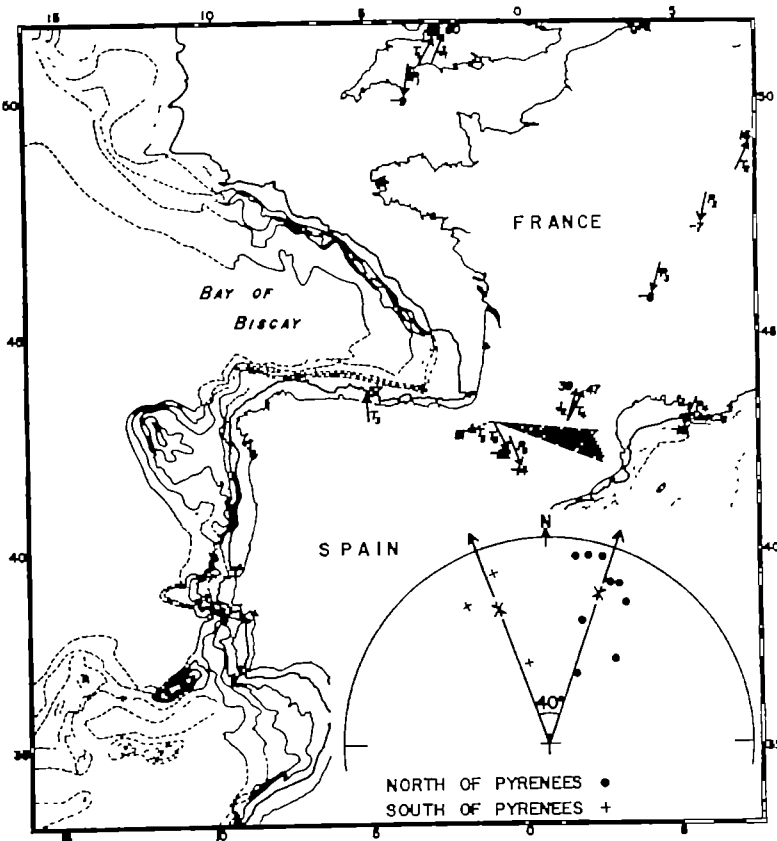

Fig. 2. Map of southern England, France and Spain showing the palaeomagnetic results for Permian, Triassic and Jurassic rocks with palaeo-inclinations. The bathymetry of the Bay of Biscay is taken from Hydrographic Office Chart No. 7650-6 which was kindly provided by the Hydrographer of the Navy. The submarine contours are 100, 500, 1,000, 1,500, 2,000 and 2,500 fathoms. The inset shows the remanent vectors plotted on a Schmidt equal area projection. The vector means are shown (x) and the difference in the mean declinations may be compared with the opening of the Bay of Biscay

Table 1

North of Pyrenees			South of Pyrenees		
No.	Decl.	Ref.	No.	Decl.	Ref.
$J_1$	23	6	$T_1$	353	8
$J_2$	16	5	$T_2$	330	15
$T_1$	30	4	$P_1$	343	16
$T_2$	25	5, 7, 8			
$T_3$	29	5	Mean	343 ± 9	
$P_1$	9	9, 10			
$P_2$	18	11			
$P_3$	17	11			
$P_4$	22	12, 13, 14			
Mean	20 ± 7		Difference	88 ± 16	

If Spain has rotated with respect to France, one might expect to see some effect in the topography of the ocean floor. One such effect may be seen along the continental edge of France at latitude 47° 5' N., longitude 12° W. Here the contours change direction and are at right angles to the general north-westerly direction of the continental edge. This is at the place where the north-west corner of Spain would be if rotated back to its original position.

Clearly, it would be desirable to have more palaeomagnetic results from Spain and to test the hypothesis further, but it should be remembered that there may be an alternative explanation of the palaeomagnetic results. Some geologists working in the Pyrenees find it difficult to reconcile the rotation of Spain with the structural geology of the Pyrenees mountains<sup>17</sup>. It could be that Spain, before continental drift, was not part of the European landmass and it would therefore be valuable to obtain and compare more palaeomagnetic results for Spain with those from North Africa when they become available. If Spain was at some time not part of Europe, this would mean that the agreement between the bathymetry and the presently available palaeomagnetic results from north and south of the Pyrenees is fortuitous, which seems a little unlikely. A further and perhaps better test for the rotation would be to compare some carefully located sea or air total intensity magnetic profiles for the west coast of France and the north coast of Spain. It is hoped to be able to do this in the near future.

I thank Prof. E. Thellier, University of Paris, Prof. L. U. de Sitter and Dr. Peter May of the University of Leiden for their advice and assistance.

## PHYSICS

### Effective Atomic Numbers of Heterogeneous Materials

For a single element, the three  $\gamma$ -ray processes—photoelectric, Compton and pair production, can be expressed as a function of photon energy  $h\nu$  and the atomic number  $Z$  of the element. At a given photon

energy, the interaction is proportional to  $Z^n$  where  $n$  is between 4 and 5 for the photoelectric effect, 1 for the Compton effect, and 2 for pair production<sup>1,2</sup>. For the purposes of  $\gamma$ -ray attenuation, a heterogeneous material, consisting of a number of elements in varying proportions, can be described as a fictitious element having an effective atomic number  $Z_{eff}$ . In the study of the X-ray energy absorption of certain biological specimens Spiers<sup>3</sup> used the expression  $Z_{eff}^{2.34} = \sum \alpha_i Z_i^{2.34}$ , where  $Z_i$  is the atomic number of the  $i$ th element and  $\alpha_i$  its fractional electronic content. More recent measurements<sup>4</sup> favour a value of 3.1 instead of 2.94 for the exponent for  $Z_{eff}$ . Glasser<sup>5</sup>, in radiological studies, used the expression  $Z_{eff}^3 = \sum p_i Z_i^3 / \sum p_i Z_i$ , where  $p_i$  is the fractional part by weight of the whole mixture occupied by the element the atomic number of which is  $Z_i$ . Extending this idea of the effective atomic number of a material for specific radiation, Hine<sup>6</sup> pointed out that there is a different effective atomic number, for each absorption process in a heterogeneous material, but he could obtain expressions only for the photoelectric and pair production processes as  $Z_{eff}^{2.34} = \sum \alpha_i Z_i^{2.34}$ , and  $Z_{eff} = \sum \alpha_i Z_i$ . It can easily be shown that  $p_i$  and  $\alpha_i$  are very nearly equal<sup>7</sup>. The equations of Spiers and Hine may then be expressed as  $Z_{eff}^n = \sum p_i Z_i^n$ , where  $n$  has values of 4 to 5, 1 and 2, respectively for the photoelectric, Compton, and pair production processes. Hence, an expression for the effective atomic number for the Compton effect could not be obtained. In this communication the validity of these differing expressions is examined and a single effective atomic number is suggested for a heterogeneous material.

In 1 g of a heterogeneous material the number of atoms of the  $i$ th element is  $Np_i/A_i$ , where  $N$  is Avogadro's number,  $p_i$  the fraction by weight of the  $i$ th element in the material and  $A_i$  the atomic weight of the  $i$ th element. The total number of atoms in 1 g of material is  $N(\sum p_i/A_i)$ . The number of electrons of the  $i$ th element in 1 g of material is  $Np_i Z_i/A_i$ , and therefore the total number of electrons in 1 g of material is  $N(\sum p_i Z_i/A_i)$ . Then the effective atomic number and the effective atomic weight of a heterogeneous material are  $Z_{eff} = \sum (p_i Z_i/A_i) / \sum (p_i/A_i)$ , and  $A_{eff} = 1 / \sum (p_i/A_i)$  respectively.

The values of the effective atomic number for seven heterogeneous materials (alloys, compounds and mixtures) are shown in Table 1.

Table 1. EFFECTIVE ATOMIC NUMBERS OF HETEROGENEOUS MATERIALS

	$(\sum p_i Z_i^4 / \sum p_i Z_i)^{1/4}$	$(\sum p_i Z_i^1)^{1/1}$	$(\sum p_i Z_i^2 / \sum p_i Z_i)^{1/2}$	$\sum p_i Z_i$
Plain extruded leaded brass (copper, 80; zinc, 20)	29.21	29.20	29.19	29.20
Phosphor-bronze (copper, 89.75; tin, 10; phosphorus, 0.25)	34.36	32.61	30.10	31.06
Carbon steel (iron, 98.95; carbon, 1.05)	25.98	25.91	25.08	25.79
Monel metal (nickel, 60; copper, 40; iron, 0.5; manganese, 33)	27.22	27.15	27.03	27.07
Concrete (hydrogen, 0.56; oxygen, 49.56; magnesium, 0.24; sodium, 1.71; aluminium, 4.56; silicon, 31.35; sulphur, 0.12; potassium, 1.92; calcium, 8.26; iron, 1.23)	14.76	13.18	9.39	11.52
'Perspex' (carbon, 59.97; oxygen, 31.97; hydrogen, 8.06)	6.94	6.87	3.60	6.24
Sodium iodide (sodium, 15.84; iodine, 84.66)	53.13	50.27	32.01	46.56

The data in Table 1 show that for materials containing elements the atomic numbers of which do not differ greatly, all the expressions give similar values for the effective atomic number. For materials containing very light elements such as hydrogen (for example, 'Perspex') and for materials containing elements of very widely differing atomic numbers (for example, NaI), different values are obtained for the effective atomic number. It is observed that the effective atomic number for the photoelectric effect is always greater than for pair production, in agreement with Hine's suggestion. We conclude that for a heterogeneous material different effective atomic

numbers for different  $\gamma$ -ray processes may be required; they can be approximated to a single effective atomic number  $Z_{eff} = \epsilon(p_i Z_i / A_i) / (\epsilon(p_i / A_i))$ . Since the Compton effect is the predominant process at intermediate energies, this single effective atomic number could be considered to represent the effective atomic number for the Compton effect. The expressions  $Z_{eff} = \epsilon(p_i Z_i / A_i) / (\epsilon(p_i / A_i))$  and  $A_{eff} = 1 / (\epsilon(p_i / A_i))$  for heterogeneous materials are also useful in geophysical studies<sup>1,2</sup>.

### Reduced Absorption of Light at High Laser Power Densities

In experiments with pulsed lasers, methylene blue has been used frequently as a dye to absorb the energy<sup>1</sup>. In conjunction with heating experiments we measured the laser energy (giant ruby pulse) transmitted through a methylene blue solution and noticed a higher transmission than is derivable from ordinary spectrophotometric data<sup>2</sup>.

To examine this photobleaching more closely we used the 633-m $\mu$  line of a He-Ne-CW-laser and collimated its output to about 0.1 mm<sup>2</sup> along a light path of 10 mm in a quartz cell containing the solution. Convection and diffusion were reduced by enclosing the exposed volume in a cylinder. To assure linear response of the photodetector the power density behind the cell was attenuated. A mechanical shutter between cell and CW-laser initiated the illumination. The following solutions were investigated in some detail: (I)  $2 \times 10^{-3}$  M methylene blue in 0.1 M triethanolamine, pH 7.3; (II)  $4 \times 10^{-3}$  M methylene blue in 0.1 M triethanolamine, pH 7.3; (III)  $4 \times 10^{-3}$  M methylene blue in 0.1 M acetate, pH 5.0; (IV) solution II plus 0.01 M ferrihexacyanide.

The transmissions of these solutions,  $S_1/S_0$ , measured on a Zeiss spectrophotometer at 633 m $\mu$  and directly on the described apparatus at a low light level, were 13.7 per cent for solution I and 3 per cent for the remaining ones. When the shutter is opened at high light level, the signal increases from the initial level  $S_1$  to a new steady value  $S_2$  (Fig. 1). Fig. 2 shows the (final)  $S_2$ -values as a function of  $S_0$ , demonstrating clearly the effects of high-power densities.

Fig. 1 Percentage transmission as a function of time in experiment with solution II (rise-time 0.3 sec), the shutter is opened at  $t=0$ . The parameter  $S_0$  represents the incident power density. A neutral density filter (10.8 per cent transmission) is inserted alone for calibration and for demonstration of the linear response of the detection system.

Fig. 2 The transmitted power density finally reached,  $S_2$  (about 2 sec after shutter was opened) as a function of the incident power density,  $S_0$ . Two different solutions are used (I and II).  $S_1/S_0 = 1$  corresponds to 'no methylene blue'.

In a later series of experiments (not included in the graphs of this communication), we increased the power density to about 6 W/cm<sup>2</sup> and obtained for solution I a transmission change of  $S_2/S_1 = 4$  and for solution II one of  $S_2/S_1 = 14$  with rise-times of about 2 sec. When the illuminating power density was switched down to 10 per cent by a neutral density filter, the transmitted signal decayed from 0.1  $S_2$  to a value which reached 0.1  $S_1$  within a factor of  $1.3 \pm 0.2$  (exp. fall-time 1-2 sec). Solutions III and IV showed  $S_2 - S_1 = 0$ , at all power-levels ( $< 6$  W/cm<sup>2</sup>).

The experiments show that triethanolamine is necessary for the appearance of  $S_2 - S_1 \neq 0$ . The experiments seem to indicate the presence of a long-lived complex intermediate, involving triethanolamine and appearing possibly (quenching by ferrocyanide) via singlet-triplet transitions<sup>3-5</sup>.

The appearance of this intermediate complex may be described by a differential equation, consisting of a (first) generating term and a (second) decay term. If  $c_M^0$  represents the analytical (molar) concentration of methylene blue,  $c_X$  the (instantaneous molar) concentration of the intermediary compound X, and  $\tau$  the time constant, with which X decays to the ground state, we may write:

$$\frac{dc_X}{dt} = \frac{10^3 P_0}{N_A h \nu r^2 \pi} (1 - \exp[-\alpha M(c_M^0 - c_X)b]) - \frac{c_X}{\tau} \quad (1)$$

when  $P_0$ , laser input power (W),  $= S_0 r^2 \pi$ ;  $r^2 \pi$ , cross-sectional area of light beam in solution (cm<sup>2</sup>);  $b$ , length of light beam in solution (cm);  $N_A h \nu$ , energy of 1 mole of light quanta in W sec mole<sup>-1</sup>;  $\alpha M$ , natural molar extinction coefficient of methylene blue at 633 m $\mu$  ( $M^{-1}$  cm<sup>-1</sup>). Equation (1) considers only the reversible part of the photolysis, assumes quantum yield of unity, and neglects concentration distribution (as well as the heating and the diffusion out of the constricted volume).

Four limiting cases of equation (1) may be considered: (a)  $dc_X/dt = 0$ , corresponding to the 'steady state'-condition, reached in the horizontal portions of the curves in Fig. 1; (b)  $c_X \ll c_M^0$ , allowing treatment of the 'linearized case', presented in Fig. 1 by the curve with  $S_0 = 0.2$  W/cm<sup>2</sup>; (c)  $c_X = 0$ , equivalent to the 'starting condition', giving the slope (in Fig. 1) of the curve at the intercept with the ordinate; (d)  $P_0 \rightarrow 0$  at the moment of reducing the input power to non-photolytic levels, when the first term vanishes and  $\tau$  is directly obtainable from the decay curve.

Above, a type of photo-stationary method is described, which is new in so far as changes in the population of the singlet ground-state are directly observed. This type is

quite different from that where processes competing with fluorescence emission are observed<sup>4</sup>.

## METALLURGY

### Influence of Pre-plated Coatings on the Morphology of the Intermetallic Layer in Tinplate

In the manufacture of electrolytic tinplate, a tin coating is electro-deposited directly on to steel. The plated strip is then heated to above the melting point of tin (232° C) and quenched in water. During this treatment cycle a layer of the intermetallic compound FeSn<sub>3</sub> (about 0.15μ thick) is formed at the steel-tin interface<sup>1</sup>.

The intermetallic compound has been shown to have an important influence on the protective value of the coating, particularly with certain canned foods<sup>2,3</sup>. Recent work<sup>4</sup> has also shown that protection is enhanced by more complete coverage of the steel by the intermetallic compound and that the degree of coverage may be associated with the morphology of the FeSn<sub>3</sub> crystallites.

The extent to which complete coverage is achieved depends primarily on the number of nucleation sites for the compound crystallites since, under normal manufacturing conditions, the time available for crystal growth is less than about 3 sec. Under such conditions the crystallites appear as a network of prisms, generally arranged in colonies which correspond epitaxially to the grain directions of the ferrite substrate.

G. G. Kamm *et al.*<sup>5</sup> have suggested that nucleation of compound crystallites is hindered by the presence of surface oxides on the steel prior to plating and have proposed reducing this by pre-plating with tin from an alkaline electrolyte. Complex heat-treatment cycles may also have the effect of modifying the crystal structure of the compound<sup>6-8</sup>.

As part of an investigation in progress at the Tin Research Institute, it has now been found that the

Fig. 1. Intermetallic compound—no undercoat ( $\times 6,000$ )

Fig. 2. Intermetallic compound—steel pre-plated with tin-nickel ( $\times 6,000$ )

Fig. 3. Intermetallic compound—steel pre-plated with nickel ( $\times 6,000$ )

nucleation characteristics and the crystal habit of the intermetallic compound on tinplate can be markedly influenced by pre-plating the steel with an extremely thin coating of another metal or alloy. The range of undercoating materials studied included iron, lead, tin-nickel, nickel and palladium, but the most significant results were achieved with electro-deposited tin-nickel alloy and nickel.

In contrast to the normal type of compound layer formed when no undercoat is used (Fig. 1), the presence of a tin-nickel or nickel undercoat (0.025μ thick) causes the intermetallic compound to grow in the form of rounded equi-axed crystals (Figs. 2 and 3). The coverage of the base steel seems virtually complete and accelerated corrosion tests appear to indicate a four-fold improvement in corrosion resistance for the materials prepared with tin-nickel or nickel as compared with tinplate prepared without an undercoat. Both nickel and tin-nickel appear to be particularly potent in their influence on the morphology of FeSn<sub>3</sub>.

We thank Dr. W. K. Armitage of Aeon Laboratories for the preparation of the electron micrographs.

### Interaction of Spinel Crystals and Chromium Nitride in Chromium

It has been amply demonstrated that normally brittle metals exhibit substantial ductility at low temperatures when interstitial impurity levels are extremely low. This is particularly true for interstitial nitrogen in chromium<sup>1</sup>. As little as 15 p.p.m. nitrogen has been reported to embrittle chromium<sup>2</sup>.

A rather unexpected result occurs when a spinel-forming oxide such as magnesium oxide is added to chromium. The composite mixture exhibits ductility at room temperature after hot-working for densification<sup>3</sup>.

X-ray experiments confirm that magnesium-chromite spinel forms as magnesium oxide combines with oxygen and chromium in the powder mixture. We believe that the spinel formed in this manner enhances ductility by absorbing nitrogen contained in the chromium.

A composite containing 93.5 per cent electrolytic chromium, 0.5 per cent titanium, and 8 per cent magnesium oxide has been examined in an experiment involving exposure to nitrogen in order to investigate the effect produced by the spinel. The composite mixture was first fabricated by mixing powders of chromium, titanium and magnesium oxide, compacting hydrostatically, sintering, and then extruding.

The extruded composite mixture contains larger amounts of interstitials (120 p.p.m. nitrogen, for example) than the maximum allowable limits normally quoted for ductility. Nevertheless, this material demonstrates ductility in tension and in bending at room temperature. The physical properties of the material, including notch tensile results, have been previously reported<sup>4</sup>.

Sintered and wrought chromium composite material containing magnesium-chromite spinel, as explained here, was exposed at 1,200° C in argon containing 100 p.p.m. nitrogen, quenched in water, and examined metallographically. The first electron micrograph (Fig. 1) shows the structure. Fine nitride needles are present in the matrix. The sample was then aged 1 h at 100° C, resulting in growth of the nitride particles, as seen in Fig. 2. The material was completely embrittled at this stage. It was then held for 4 h at 1,425° C in moderate vacuum. The resulting structure is shown in Fig. 3. The photomicrograph demonstrates that the nitride has completely disappeared from the matrix.

It would seem likely that the spinel crystals absorbed the precipitated nitride. The photomicrograph offers evidence to this effect. A very fine amorphous material has collected around the ceramic grains. This material was removed in the process of replicating the polished and etched specimen for the electron microscope. No

Fig. 1. Chromium nitride needles after quenching (electron micrograph replica)

Fig. 2. Chromium nitrides after 100° C ageing (electron micrograph replica)

Fig. 3. Reaction product at oxide particle after 1,425° C solution treatment (electron micrograph with extraction technique)

electron diffraction pattern could be obtained from it, indicating that it was amorphous or composed of very small crystals. The composite was ductile and could be bent at room temperature after this heat treatment.

It is possible that the chromium nitride would break down at 1,425° C and go into solution, the nitrogen recombining at the metal surface or simply subliming. Accordingly, a sample of pure electrolytic chromium, containing no magnesium oxide, was fabricated, extruded, and exposed to nitrogen in the same manner. Nitrides were still present in quantity after the 1,425° C heat treatment, including heavily nitrated grain boundaries.

In conclusion, then, it can be said that a dispersed spinel phase exhibits the important property of chemically rendering the matrix free from nitride precipitates. This effect further lowers the amount of nitrogen contained in the matrix to values low enough to promote room temperature ductility.

I thank Mr. Conrad Herald for the electron micrographs.

## CHEMISTRY

Cation Distribution in Ulvöspinel  $\text{Fe}_2\text{TiO}_4$ 

RECENTLY we have considered it of interest to examine several spinel oxides containing iron, using the Mössbauer effect in the isotope iron-57, in order to determine the cationic oxidation state and site distribution<sup>1</sup>. A case in which such information might be valuable is the oxide  $\text{Fe}_2\text{TiO}_4$ . Since the original X-ray intensity investigation of Barth and Poniak<sup>2</sup> this spinel has been considered to possess the inverse arrangement  $\text{Fe}[\text{TiFe}]_2\text{O}_4$ . However, the determination of cation distribution for an oxide with cations of such similar scattering coefficients is not easy. In addition the calculated intensity value for the 135 reflexion given by those authors for the normal arrangement is in error by several orders of magnitude. The inverse arrangement is favoured for a 2-2-4 spinel on the basis of electrostatic considerations<sup>3</sup>, and the known ferrimagnetic properties of  $\text{Fe}_2\text{TiO}_4$  (Curie point 120° K (ref. 4)). The normal arrangement  $\text{Ti}[\text{FeFe}]_2\text{O}_4$  requires  $\text{Ti}^{4+}$  ions on tetrahedral *A* sites. This is uncommon, but has been observed by Gorter<sup>5</sup> in the material:

on the basis of saturation magnetization and *g*-factor determinations.

A sample of  $\text{Fe}_2\text{TiO}_4$  was prepared by calcining a  $\text{TiO}_2$ - $\text{Fe}_2\text{O}_3$  mixture in a CO-CO<sub>2</sub> atmosphere as used by Kunnmann *et al.*<sup>6</sup>. The lattice parameter was determined as  $8.529 \pm 0.003$  Å in good agreement with the figure of 8.53 Å given by Akimoto<sup>4</sup>. The X-ray diagram also indicated the presence of ~1 per cent ilmenite which, by the formation of a proportionate amount of  $\text{Fe}_2\text{O}_3$ , could account for the sample possessing an overall ferromagnetism. (We are grateful to Dr. T. I. Barry for the magnetic measurements.) The room-temperature Mössbauer spectrum of this sample obtained with equipment described elsewhere<sup>1</sup>, and using a source of cobalt-57 in stainless steel, is shown in Fig. 1. The derived isomer shift and quadrupole splitting values are  $1.08 \pm 0.06$  mm sec<sup>-1</sup> and  $1.85 \pm 0.06$  mm sec<sup>-1</sup> respectively. Within the limits of error these values are identical to those obtained earlier for  $\text{FeAl}_2\text{O}_4$  with  $\text{Fe}^{2+}$  on tetrahedral *A* sites<sup>1</sup>. Since the inverse arrangement is favoured for  $\text{Fe}_2\text{TiO}_4$  (possibly with some of the  $\text{Ti}^{4+}$  ions on *A* sites), this result indicates that *A*- and *B*-site  $\text{Fe}^{2+}$  in  $\text{Fe}_2\text{TiO}_4$  gives rise to identical isomer shifts and quadrupole splittings which may limit the use of the effect in similar situations. The presence of  $\text{Fe}^{2+}$  quadrupole interaction in  $\text{Fe}_2\text{TiO}_4$  and  $\text{FeAl}_2\text{O}_4$  but not in  $\text{FeV}_2\text{O}_4$  and  $\text{FeCr}_2\text{O}_4$  indicates that

Fig. 1. Room temperature Mössbauer absorption spectrum for  $\text{Fe}_2\text{TiO}_4$ .

the electric field gradient at a nucleus at a given site in a spinel is dependent on the magnetic nature of the cations at neighbouring sites.

## Superficial Ion-exchange Chromatography

RECENTLY the techniques of gas chromatography have been applied to chromatography in the liquid phase to separate small quantities of mixtures very rapidly. Techniques have been described for adsorption chromatography<sup>1</sup>, partition chromatography<sup>2</sup>, and ion-exchange chromatography<sup>3</sup> where the inner surface of a capillary tube was coated with a liquid ion-exchanger.

In this laboratory, beads of cross-linked polystyrene which bear ion-exchange groups only in a shallow 'surface' layer have been used for superficial ion-exchange chromatography. The ion-exchange groups are not limited to amino-groups, and resins with superficial sulphonic acid groups and with superficial quaternary ammonium groups have been used successfully. The resins are expected to be as stable as the normal polystyrene resins, and columns packed with them should last indefinitely.

In normal ion-exchange chromatography the best results are obtained with very small particles and very low flow rates<sup>4</sup>, partly because the diffusion of ions into and out of the particles is slow. In superficial ion-exchange chromatography the distance the ions have to diffuse into the particles is greatly reduced, and rapid flow rates may be used with beads of convenient size. The beads used to obtain the elution curves shown in Fig. 1 had a mean diameter of 0.24 mm, and were surface-sulphonated to a capacity of 5.3  $\mu\text{equiv./ml}$ . They were packed in a 45-in. column, 6 mm internal diameter, and eluant was pumped through at a rate of 6 ml./min. Molar solutions of metals or 1 per cent solutions of dyes were injected in quantities of 1-10  $\mu\text{l}$ . Curve A shows the elution with 0.3 N hydrochloric acid of a mixture of copper and iron, and the tailing of the iron which occurs in this system. The tailing was reduced by gradient elution (curve B), and the separation was complete in 14 min. These curves should be compared with those obtained for the same metals on 'AG 50X8' by elution with more concentrated acid<sup>5</sup>. Curve A was not appreciably altered by faster or slower flow rates, and the tailing was not improved when a 15-in. column packed with beads of diameter 0.08 mm was used.

In practice, most ion-exchange separations depend less on the efficiency of the column than on the choice of a suitable eluant, which is often a complexing agent<sup>6</sup>. For the separation of metals it should be possible to prepare resins with superficial chelating groups and elute different metals with eluants of different pH. In this way the main drawback of chelating resins, which is the slow diffusion within the particles, could be avoided. However, the chief application of superficial ion-exchange chromatography is likely to be the rapid separation and characterization of organic acids and bases. Curve C shows the separation of two basic dyes, methylene blue (the first peak) and Janus green (the second peak). These dyes could not be eluted with the same eluant (5 N

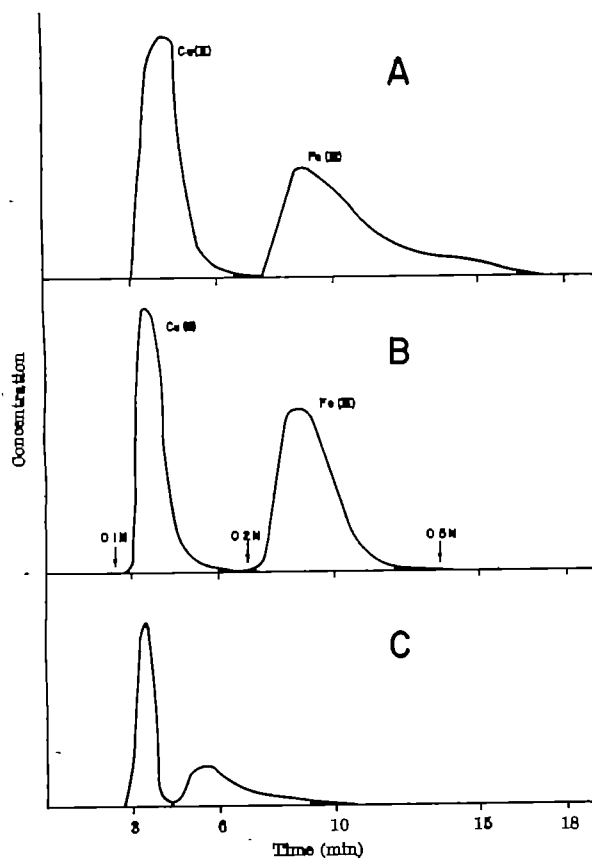

Fig. 1

hydrochloric acid in 6 per cent alcohol) from a normal resin ('AG 50X2'). Similarly, acid dyes have been separated on a superficial anion-exchange resin. For the convenient separation of colourless substances a continuous method of detection would be required. Ultra-violet absorption of the effluent might be measured in many cases, or the type of detector described by Stouffer *et al.*<sup>7</sup> might be suitable if interference from the eluant could be avoided. It is possible to increase the capacity of the beads and use correspondingly larger quantities of the mixture to suit the sensitivity of the detector.

### Low-temperature Cleavage of Ethers

THE cleaving of an ether usually requires the use of a vigorous reagent such as an anhydrous mineral acid, an organic acid halide or anhydride, a Lewis acid, or an organometallic compound. Frequently heating for prolonged periods is necessary.

In examining the chemistry of boron, it has been found that, in conjunction with a halogen such as (by preference) iodine, boranes<sup>1</sup> and metal borohydrides<sup>2</sup> will destroy the

hydroxyl groups of alcohols, which are converted into organic halides. Although diborane on its own does not normally react with ethers near room temperature, except possibly to form a very loose addition compound, in the presence of free halogen a comparable reaction occurs with ethers<sup>1</sup>. An oxygen-carbon link is ruptured, the oxygen attaching itself to the boron while the carbon links up with halogen. Thus anisole gives methyl iodide and triphenyl borate, from which phenol is immediately obtained on subsequent hydrolysis in the cold:

Attention is now directed to this reaction as a means of cleaving ethers under milder conditions than hitherto possible. By it, a rapid, smooth and complete cleavage can be effected, usually at room temperature or even below. The ether must be dry. The relative amount of diborane required is small, since one molecule cleaves six molecules of the ether. The reaction is moreover very widely applicable. The ether may be symmetric, unsymmetric, aliphatic, aromatic or cyclic. With cyclic ethers a boron ester is first produced which on subsequent hydrolysis yields the  $\omega$ -iodo derivative of an alcohol as the ultimate product, for example:

In this way 4-iodobutan-1-ol, was prepared in more than 90 per cent yield from tetrahydrofuran. Its identity was confirmed by C, H and O analysis, both on the original product and on its *p*-nitrobenzoate derivative, which had an observed melting point of 104.5° C.

In general, the cleavage reaction is efficient and rapid, and proceeds quietly to completion within minutes at room temperature. Higher boranes are inclined to react more slowly than diborane. Metal borohydrides are comparable in reactivity to diborane, although sodium borohydride is less reactive than the lithium salt. Bromine and interhalogen compounds such as iodine chloride react more vigorously than iodine, but are in general less convenient. Large excesses of reagents are unnecessary and should be avoided.

The ready availability of metal borohydrides and hence diborane implies that this method could become a useful tool in degradative organic chemistry.

### Unusual Role of Dimers in Thermal Polymerization of Chloroprene

THE dimerization products of chloroprene have been shown to consist principally of two substituted cyclohexenes and an eight-membered cyclic diene<sup>1</sup>. Carothers *et al.*<sup>2</sup> have noted the presence of a distinct oligomeric fraction in the polymerization products of chloroprene, and more recently Klebenskii *et al.*<sup>3</sup> have shown that this fraction contains both six- and eight-membered cyclic dimers. In previous kinetic studies of the thermal poly-

merization of chloroprene, no special account has been taken of the formation of dimers; it has been tacitly assumed, for example, that the rate and the observed activation energy of the thermal polymerization<sup>4,5</sup> refer to a direct polymerization of the chloroprene monomer.

Our present kinetic experiments, however, lead us to the conclusion that the above assumption is not valid, and that the thermal polymerization proceeds by an unusual mechanism.

The yields of polymer and dimers have been measured as a function of time in three chloroprene systems at 35° C: (i) pure monomer; (ii) pure monomer containing excess inhibitor; (iii) pure monomer containing a small quantity of inhibitor which is consumed during the early part of the reaction. Expressing all rates of reaction in terms of the rate of disappearance of chloroprene monomer, it is found that, within experimental error, the rate of polymerization in (i) is equal to the rate of dimerization in (ii), whereas the rate of polymerization in (ii) is zero.

During the post inhibition period in (iii) the dimer concentration falls rapidly until it reaches a low steady value similar to that observed in (i), whereas the rate of polymerization, initially large, eventually falls to a constant value comparable with that observed in (i).

The simplest explanation of the results is that polymer is actually formed by a process of dimer addition and that little or no monomer is involved in the propagation reaction. Experiments in which small quantities of monomer were added to bulk dimers at 35° C indicate that monomer, or a trace impurity associated with it, plays an essential part in the thermal polymerization reaction, most probably in the initiation process.

# Inorganic Precipitation of Calcium Carbonate from Sea-water

RECENTLY, Wells and Illing have suggested<sup>1</sup> that the so-called 'whittings' in the Persian Gulf are clouds of calcium carbonate precipitated instantaneously from sea-water that has become supersaturated with respect to calcium carbonate, owing to removal of CO<sub>2</sub> by the photosynthetic action of phytoplankton.

In order to investigate this interesting phenomenon, we have compared the composition of a 'whiting' sample collected by A. J. Wells with that of bottom sediment at a locality near the place where the whiting had formed, and with that of artificial precipitates of CaCO<sub>3</sub>. Artificial precipitation was brought about by removal of carbon dioxide both from Persian Gulf sea-water and from artificial sea-water having the same major-element composition. The mineral composition of the various samples was then determined.

The sea-water sample was placed in the bottom part of a desiccator and was constantly and rapidly stirred by a magnetic stirrer. Supersaturation was obtained either by removal of CO<sub>2</sub> or by addition of Na<sub>2</sub>CO<sub>3</sub>. Removal of CO<sub>2</sub> from the sea-water was brought about by placing a strong sodium hydroxide solution in the upper part of the desiccator. The conditions of the experiments and the approximate time necessary to form a precipitate are presented in Table 1.

Table 1

Experiment	Type of sea-water	Chlorinity (‰)	Proc. obtained by:	Approx time to form a precipitate
1	Doha Bay*	22.5	CO <sub>2</sub> -extraction	3 weeks
2	Doha Bay	22.5	Na <sub>2</sub> CO <sub>3</sub> -addition	2 weeks
3	Artificial	22.5	CO <sub>2</sub> -extraction	2.5 weeks
4	Ditto	22.5	Ditto	2 weeks
5	Ditto	22.5	Ditto	2 weeks

\* Doha Bay is located on the eastern side of the Qatar peninsula.

Table 1 shows that formation of a precipitate is not a matter of minutes but of weeks. Experiment 2 was carried out in order to make sure that the removal of CO<sub>2</sub> from the sea-water by NaOH was not the rate-determining step: a concentrated sodium carbonate solution was added to the water until the pH of the water was 8.98.

In experiment 2 the supersaturation of the water with respect to calcium carbonate is higher than the supersaturation obtained in the other experiments, because the total carbonate content (CO<sub>3</sub><sup>2-</sup> + HCO<sub>3</sub><sup>-</sup> + CO<sub>2</sub>) was greater in experiment 2. In the other experiments the total carbonate content was decreased by extraction of CO<sub>2</sub>. Clearly the CO<sub>3</sub><sup>2-</sup>-concentration reaches a higher value either by Na<sub>2</sub>CO<sub>3</sub>-addition or CO<sub>2</sub>-extraction, since each process brings about the supersaturation with respect to calcium carbonate.

In all experiments the precipitation of calcium carbonate was nothing like fast enough to balance the increasing CO<sub>3</sub><sup>2-</sup>-concentration, and the pH consequently increased. One should therefore expect an increase in pH before whiting formation starts and a drop in pH when precipitation starts. This drop in pH may be difficult to measure if precipitation is slow. However, if a precipitate does form over a large area in a matter of minutes, the drop should be detectable. Field observations, however, gave no evidence of a change in pH during whiting formation.

The precipitates which formed during our experiments were filtered, washed with a small quantity of distilled water and dried at 105° C. The whiting sample, the bottom sediment sample (fraction < 2μ) and the precipitates were examined under the microscope and analysed by X-ray diffraction.

X-ray diffraction analysis was carried out with a Philips X-ray diffractometer, using Cu-Kα radiation. The relative amounts of the various minerals present were estimated by comparing the areas of the peaks in the diffractogram, account being taken of the poor reflective power of aragonite. The values given are only semi-quantitative. As the amount of precipitate recovered in experiments 4 and 5 was too small for diffractometer analysis, Guinier X-ray diffraction photographs of these samples were therefore made. In all precipitates obtained in the laboratory only aragonite was found, except for the precipitate obtained by addition of Na<sub>2</sub>CO<sub>3</sub> to unfiltered Doha Bay water (see Tables 1 and 2). The trace amount of magnesium calcite was found to be originally present in suspension in the water supplied for this experiment. It is clear from Table 2 that the mineral compositions of whiting and bottom sediment are very similar, and that they differ appreciably from the compositions of the artificial precipitates.

Table 2. RESULTS OF X-RAY DIFFRACTION AND EMISSION SPECTROGRAPHIC ANALYSIS

Sample	Description	Sr/Ca ratio (mg/g) of water	X-ray diffraction analysis			
			Ara-gonite (%)	Calcite (%)	Mg-calcite (%)	Quartz (%)
A	Whiting (Wells, 1961)	—	70	10	15	5
B	Bottom sediment (< 2μ)	—	65	10	20	trace
C	Bottom sediment	—	70	15	10	trace
1	Proc. from Doha Bay water made by CO <sub>2</sub> -extr.	22.5	100	—	—	—
2	Ditto by Na <sub>2</sub> CO <sub>3</sub> -add.	22.5	95-100	—	trace	—
3	Proc. from artif. sea w.	65	100	—	—	—
4	Ditto	130	100	—	—	—
5	Ditto	22.5	100	—	—	—

Table 2 shows that pure aragonite was the only type of calcium carbonate to precipitate from sea-water by  $\text{CO}_2$  extraction. This finding has also been made by other workers<sup>2</sup>. Furthermore, the rate of crystallization of aragonite in these experiments was so slow (even at the unnaturally high supersaturation value achieved by adding sodium carbonate to make the solution pH 9) that such crystallization can scarcely be used to explain the rapid formation of whittings seen in the sea off Doha.

### An Experimental Determination of the Photo-ionization Cross-section of Atomic Hydrogen

ALTHOUGH many theoretical calculations of the photo-ionization cross-section of atomic hydrogen have been performed (see review by Bates<sup>1</sup>), no experimental determination of this quantity has previously been made. An experiment is being carried out here which has yielded a value for the photo-ionization cross-section of atomic hydrogen at 850.6 Å.

Atomic hydrogen is produced by flowing molecular hydrogen through a discharge tube in which an intense radio frequency discharge is run. This dissociates a large fraction of the hydrogen molecules. The mixture of atoms and molecules is then flowed quickly through an all-glass absorption cell which is attached to the exit slit of a one-metre normal-incidence vacuum monochromator. Radiation emerging from the exit slit passes down the absorption cell and is detected by a sensitized photomultiplier placed at the far end of the cell. The light source used to illuminate the entrance slit of the monochromator is similar to that described by Garton<sup>2</sup> and consists essentially of a short-duration high-current spark produced by discharging a capacitor bank. The light source is filled with low-pressure argon gas and the radiation produced by it consists mainly of emission lines of neutral and multiply ionized argon.

The intensity of the radiation emerging from the absorption cell is measured under three conditions: (i) intensity  $I_0$ , with the absorption cell evacuated; (ii)  $I_1$ , with the absorption cell filled with molecular hydrogen at pressure  $p_1$ ; (iii)  $I_2$ , with partially dissociated hydrogen in the absorption cell at total pressure  $p_2$ . The degree of dissociation  $\alpha$  is determined by the Wrede-Harteck method<sup>3</sup>.

From (i) and (ii) the photo-absorption cross-section of molecular hydrogen,  $\sigma_M$ , can be determined from the equation:

$$I_1 = I_0 \exp \left( -N\sigma_M \frac{p_1}{760} \frac{273}{T} l \right) \quad (1)$$

where  $N$  is Loschmidt's number,  $2.69 \times 10^{19}$  particles/c.c.,  $T$  is the absolute temperature of the gas (°K), and  $l$  is the length of the absorption cell (cm).

From a knowledge of  $\alpha$  and  $p_2$ , the partial pressures  $p_A$ ,  $p_M$  of atomic and molecular hydrogen can be calculated. Thus, using (i) and (iii) and the result for  $\sigma_M$  derived from (1), the photo-ionization cross-section of atomic hydrogen,  $\sigma_A$ , can be found from the equation:

$$I_2 = I_0 \exp \left( - \left\{ N\sigma_A \frac{p_A}{760} \frac{273}{T} + N\sigma_M \frac{p_M}{760} \frac{273}{T} \right\} l \right) \quad (2)$$

$p_1$ ,  $p_2$  and  $\alpha$  are measured at each end of the absorption cell and a correction for the concentration gradient along the length of the cell is applied.

Due to the difficulty in obtaining sufficient intensity at the photomultiplier to make reliable measurements, initial results have been confined to a wave-length, 850.6 Å, which corresponds to a strong emission line of the light source and a very small absorption cross-section of molecular hydrogen.

The mean value of the molecular cross-section (together with the probable error) at 850.6 Å is  $(0.213 \pm 0.010) \times 10^{-18} \text{ cm}^2$ , which is not in agreement with Cook and Metzger's<sup>4</sup> result of  $\sim 3.2 \times 10^{-18} \text{ cm}^2$  at this wave-length. This may be due to a difference in the effective resolution of the two systems; as there is no continuous absorption in this region the measured value of  $\sigma_M$  will depend critically on the resolution. Cook and Metzger used a continuum light source in conjunction with a monochromator with a pass band of 0.5 Å. Although our instrument has a similar bandpass, we used a line source and, as the width of the 850.6 Å A IV line is probably of the order of or less than 0.1 Å, our resolution is much better than the bandpass of the instrument.

The mean value of the photo-ionization cross-section of atomic hydrogen at 850.6 Å is:

$$(5.15 \pm 0.18) \times 10^{-18} \text{ cm}^2$$

This is in good agreement with the most recently available theoretical value which is given in graphical form by Bates<sup>1</sup>. At 850.6 Å the theoretical value lies between  $5.1$  and  $5.2 \times 10^{-18} \text{ cm}^2$ .

This work was initiated by Dr. R. B. Cairns and I thank him for his help during the early stages.

### Structure of Catena-di- $\mu$ -Fluorodifluoro-diaquohafnium(IV) monohydrate ( $\text{HfF}_4 \cdot 3\text{H}_2\text{O}$ )

ALTHOUGH the trihydrate of hafnium tetrafluoride and its dehydration products are stoichiometrically similar to the corresponding compounds of zirconium, it has been shown<sup>1</sup> that they are not isostructural. In general, compounds of the two elements do show identical structure (for example, the anhydrous fluorides<sup>2</sup>), and the fluoride hydrates must be particularly susceptible to differences in bond energy. The structure of  $\text{ZrF}_4 \cdot 3\text{H}_2\text{O}$  has been reported previously<sup>3</sup>, and the hafnium analogue has now been investigated.

Crystals were prepared, as previously described<sup>1</sup>, as an apparently homogeneous sample of colourless needles. Single crystal studies have, however, demonstrated the existence of two distinct species. One of these is monoclinic,  $a = 25.48$ ,  $b = 7.51$ ,  $c = 23.02$  Å,  $\beta = 150^\circ$ , 16 molecules per unit cell. Reflections are systematically absent for all  $hkl$  when  $h + k$  is odd, and for  $hkl$  with  $k$  even, when  $k/2 + 1$  is odd. Reflections with  $k$  odd are weak and are markedly diffused along  $c^*$ , thus suggesting that the structure is at least partially disordered. Our investigation has not proceeded further than the location of the hafnium atom positions.

The other modification is also monoclinic, with  $a = 6.70$ ,  $b = 10.55$ ,  $c = 7.71$  Å,  $\beta = 94^\circ$ , 4 molecules per unit cell, space group  $P2_1/a$ . The structure of these crystals had no such complications and has been solved by conventional methods. The current reliability factor, assuming isotropic thermal motion, is 0.14.

All light atoms were assumed to be fluorine for the purpose of structure factor calculation. The peak electron densities on a subsequent Fourier synthesis were 11.6, 10.7, 9.9, 9.4, 8.6, 6.7 and 6.5 electrons Å<sup>-3</sup>. The smallest

Fig. 1

atom is not directly linked to a hafnium. It makes four tetrahedrally disposed approaches of length 2.68–2.87 Å to other light atoms and can be designated a water molecule. The remaining light atoms are co-ordinated to the hafnium, forming linear chain molecules as shown in Fig. 1. The bridging atoms are the largest peaks and by analogy with similar structure (for example,  $\text{UF}_6$  (ref. 4) with which  $\text{HfF}_6$  is isomorphous;  $\text{ZrF}_6 \cdot 3\text{H}_2\text{O}$  (ref. 3);  $\text{K}_2\text{ZrF}_6$  (ref. 4)) are assumed to be fluorine. The assignment of the remaining atoms, as shown, has been made solely on peak height and can only be regarded as tentative.

The co-ordination polyhedron about each hafnium is a slightly distorted anti-prism, and is very similar to that observed for  $\text{ZrF}_6 \cdot 3\text{H}_2\text{O}$  (ref. 3). The two differ in that the latter is a dimer, with the metal atoms linked by one fluorine double bridge, whereas in this structure each hafnium is linked to two others by fluorine bridges, thus forming a polymeric chain. It is then mere coincidence that the presence of an extra molecule of water of crystallization gives the two compounds identical stoichiometry.

## BIOCHEMISTRY

### Mechanism of Iron Stimulation of the Enzymatic Activity of Ceruloplasmin

It is well established that certain metal ions stimulate the oxidase activity of the copper-containing protein ceruloplasmin with aromatic diamines and diphenols<sup>1-4</sup>. Using *N,N*-dimethyl-*p*-phenylenediamine as substrate, Curzon<sup>3</sup> observed stimulation of this activity by several transition metal ions, for example,  $\text{Fe}^{2+}$ ,  $\text{Ni}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Co}^{2+}$  and  $\text{Fe}^{3+}$ . By far the most active metal ion was  $\text{Fe}^{3+}$ . Conspicuous by its lack of stimulatory effect was  $\text{Cu}^{2+}$ . Levine and Peisach<sup>4</sup> confirmed Curzon's observation regarding the potent stimulatory effect of  $\text{Fe}^{3+}$  but felt that stimulation due to the other metals can be explained in terms of  $\text{Fe}^{3+}$  contamination. In further investigations of this phenomenon, Peisach and

Levine<sup>5</sup> showed that  $\text{Fe}^{2+}$  stimulated ceruloplasmin activity when the functional groups of the substrate were *para* related (for example, *p*-phenylenediamine (PPD), hydroquinone, but not when the functional groups were *ortho* related (for example, *o*-phenylenediamine, catechol).  $\text{Cu}^{2+}$ , on the other hand, was stimulatory when the functional groups of the substrate were *ortho* related but not *para* related. Peisach and Levine proposed that enzyme copper can form either an active complex with the  $\pi$ -electrons of the aromatic ring<sup>6</sup> or an inactive complex with the functional groups of the substrate. Metals which stimulated the oxidase activity could act by complexing with the functional groups of the substrate, thus preventing the formation of the inactive enzyme-substrate complex.

To test this hypothesis, the effect of  $\text{Fe}^{2+}$  was measured in ceruloplasmin systems using PPD and several of its derivatives as substrates. Experiments were performed spectrophotometrically using a highly purified preparation of pig ceruloplasmin<sup>4</sup> ( $A_{410}/A_{310} = 0.042$ ). The medium contained 0.1 M sodium acetate buffer, pH 5.5, 0.83 mM substrate, 0.023  $\mu\text{M}$  pig ceruloplasmin, and varying amounts of  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_6$ . Enzyme rates were determined by following the increase in absorbancy at 490 m $\mu$  for PPD, at 550 m $\mu$  for *N,N*-diethyl-PPD, and at 610 m $\mu$  for *N,N,N',N'*-tetramethyl-PPD. The results are shown in Fig. 1. For all three substrates, increasing the concentration of  $\text{Fe}^{2+}$  causes an increase in the reaction rate. An optimum  $\text{Fe}^{2+}$  concentration is attained, and further increases in metal ion concentration bring about an inhibitory effect. Inhibition at high concentrations has been observed for most transition metal ions, regardless of whether or not they are stimulatory at low concentrations<sup>4,7</sup>. Alkyl substituents on one amino-group of the substrate, such as in *N,N*-diethyl-PPD, decrease the maximum stimulatory effect of  $\text{Fe}^{2+}$ , while substituents on both amino-groups, such as in *N,N,N',N'*-tetramethyl-PPD, decrease the effect even further. There is less  $\text{Fe}^{2+}$  stimulation of ceruloplasmin oxidase activity in those cases where there is steric-interference of  $\text{Fe}^{2+}$  complex formation. Further evidence for our hypothesis is given in Table 1. A series of experiments were performed similar to the one illustrated in Fig. 1 in which varying amounts of  $\text{Fe}^{2+}$  were added to the reaction mixture. For each experiment a different PPD concentration was used, and the concentration of  $\text{Fe}^{2+}$  required for maximal stimulation was determined in each case. Within the range

Fig. 1 Effect of  $\text{Fe}^{2+}$  on the ceruloplasmin-catalysed oxidation of aromatic diamines. PPD, *p*-phenylenediamine; D-PPD, *N,N*-diethyl-*p*-phenylenediamine; T-PPD, *N,N,N',N'*-tetramethyl-*p*-phenylenediamine.

Table 1. RATIO OF  $\text{Fe}^{2+}$  CONCENTRATION TO PPD CONCENTRATION AT MAXIMAL STIMULATION OF CERULOPLASMIN-CATALYZED OXIDATION

PPD concentration (mM)	( $\text{Fe}^{2+}$ )/(PPD) at maximum stimulation
50	0.08
30	0.017
10	0.01, 0.006
3	0.01

of PPD concentrations reported here, the ratios of  $\text{Fe}^{2+}$  to PPD concentrations were in the same order of magnitude. This strongly implies that a specific  $\text{Fe}^{2+}$ -substrate complex is involved in the stimulation of ceruloplasmin activity. It is postulated that a similar mechanism is operative for  $\text{Cu}^{2+}$  stimulated systems.

### Effect of Alloxan-Diabetes on the Activity of Citrate Cleavage Enzyme in Adipose Tissue

It has been known since the work of Stetten and Boxer<sup>1</sup> that glucose is rapidly converted into lipid in tissues of well-fed animals, while lipogenesis is greatly depressed in tissues of diabetic animals. Neither liver slices nor adipose tissue from diabetic rats can convert glucose labelled with carbon-14 into fatty acids<sup>2,3</sup>. The rate of synthesis of long-chain fatty acids from glucose by isolated tissues removed from normal animals is actually more rapid in adipose tissue than in liver, whether expressed on a wet weight or a protein basis<sup>4</sup>. The relatively high rate of lipogenesis in adipose tissue, coupled with its abundance, has suggested that this tissue may be of predominant importance in the *in vivo* synthesis of lipid<sup>4,5</sup>. While there has been extensive work on the enzymatic lesions in fatty acid synthesis in the livers of alloxan-diabetic rats, adipose tissue has not been so widely studied<sup>6,7</sup>.

Recent work has shown that citrate has an important regulatory function in both carbohydrate and fat metabolism<sup>8,9</sup>. Citrate can provide a source of acetyl-coenzyme A (CoA) for fatty acid synthesis in the soluble fraction of the cell by means of the citrate cleavage enzyme:

In the livers of alloxan-diabetic rats this enzyme is decreased to approximately half the control value<sup>8</sup>. In view of these observations and the important part that this enzyme is thought to play in the control of lipogenesis<sup>10</sup>, it seemed of interest to investigate its activity in adipose tissue which is specifically adapted to the formation of fat. An additional advantage in investigations on adipose tissue is the absence of such alternative pathways of metabolism of acetyl-CoA as cholesterol synthesis.

The changes in the activity of citrate cleavage enzyme in the liver and adipose tissue of alloxan-diabetic rats are shown in Fig. 1. In agreement with the results of Kornacker and Lowenstein<sup>8</sup>, it was found that the citrate cleavage enzyme in liver fell in the alloxan-diabetic group to approximately half the control value. The differences were highly significant whether expressed as activity/g liver, as activity/mg protein or as total activity in the

Fig. 1. Changes in the activity of citrate cleavage enzyme in the liver (left) and adipose tissue (right) of alloxan-diabetic rats compared to controls. Adult male albino rats were starved for 48 h and alloxan was given subcutaneously in a dose of 20 mg/100 g body weight. The rats were then given free access to food and water and were maintained on protamine zinc insulin (Boots) 2 units daily for 4 days. Thereafter no further treatment was given and the rats were killed 3 weeks after the last dose of insulin when the blood sugar values of the alloxan-diabetic rats were all greater than 350 mg/100 ml. blood. Controls of the same age and body weight were used. All rats were allowed food *ad lib*. The activity of the citrate cleavage enzyme was estimated in liver and paired epididymal fat pads by the method of Kornacker and Lowenstein<sup>8</sup>. The results, as  $\mu\text{moles acetyl-CoA formed/mg liver protein/h}$  or as  $\mu\text{moles acetyl-CoA formed/mg adipose protein/h}$ , for alloxan-diabetic rats are given as percentage change with respect to the control values. Open columns represent control values, hatched columns diabetic values. The control values for liver and adipose tissue based on the tissue protein content are respectively  $0.7 \pm 0.04$  and  $4.1 \pm 0.7$ . These activities are equivalent to a rate of acetyl-CoA formation from citrate of 137  $\mu\text{moles/g liver/h}$  and 120  $\mu\text{moles/paired epididymal fat pads/h}$  (average weight of paired fat pads of control rats  $2.01 \pm 0.25$  g).

whole organ. The changes in adipose tissue were, however, even more striking. In the alloxan-diabetic rats the enzyme activity fell to only about 18 per cent of the control value. Similar results were obtained when the data were expressed as total activity in the two epididymal fat pads or as activity/mg tissue protein. In view of the very striking changes in the weight of the adipose tissue due to the depletion of the fat content in diabetes, the results are probably not meaningful when expressed as activity/g tissue.

The present observation that, in diabetes, citrate cleavage enzyme of adipose tissue falls more strikingly than that of liver may be considered in the light of the different functions of these tissues. While the main function of adipose tissue would seem to be the formation, storage and release of fatty acids, liver has many functions in which acetyl-CoA is required. Among these functions requiring acetyl-CoA the formation of cholesterol is of importance and it has been shown that the rate of formation of this is not diminished in alloxan-diabetic rats<sup>11</sup>. Consistent with this observation is that direct measurements have shown that acetyl-CoA content of liver is almost unchanged in diabetic rats<sup>11</sup>. Further, in the present experiments, parallel measurements of enzymes of the pentose phosphate pathway (glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase) in liver and adipose tissue have shown a more marked fall in the latter tissue; again this may be correlated with the greater decline in reductive synthetic processes. The fall in citrate cleavage enzyme could be an important factor in the accumulation of citrate within the liver which is known to occur in alloxan-diabetes and starvation<sup>8</sup>. Accumulation of citrate within the cell can have a complex action on the control and direction of both fatty acid synthesis and carbohydrate metabolism. Citrate, in addition to being a precursor for acetyl-CoA, can also activate acetyl-CoA carboxylase, the rate-limiting step in fatty acid synthesis from acetyl-CoA

(ref. 12). In diabetes this stimulatory effect is, presumably, counteracted by the fall in activity of acetyl-CoA carboxylase and fatty acid synthetase and by the inhibitory action of long-chain acyl-CoA derivatives<sup>4</sup>. These effects could also be related to the known action of citrate in inhibiting phosphofructokinase<sup>14</sup>. The inhibition of this enzyme, which is an important control point in the glycolytic pathway, could lead to a decrease in the rate of formation of  $\alpha$ -glycerophosphate and to the esterification of fatty acids. Howard and Lowenstein<sup>14</sup> and Tzur, Tal and Shapiro<sup>15</sup> have pointed out the key role of  $\alpha$ -glycerophosphate in the regulation of fatty acid synthesis.

Many of these control mechanisms have been demonstrated only in liver. The very marked fall in citrate cleavage enzyme in adipose tissue suggests that a similar sequence of events may also occur in this tissue.

### Effect of Anionic Polyelectrolytes on the Formation and Composition of Plasma Euglobulins

It is historically interesting that euglobulin, the fraction spontaneously precipitating from diluted acidified serum, was the first serum protein fraction to be investigated<sup>1</sup>. There is evidence that these fractions contain insoluble complexes resulting from electrostatic interaction between chondromucoprotein<sup>2</sup>, negatively charged above pH 2 due to dissociated carboxyl and sulphate groups on the chondroitin sulphate moiety, and proteins positively charged at plasma pH values below their isoelectric points, dissociation into soluble components occurring at pH values above those at which they were precipitated<sup>3,4</sup>. The amount of euglobulins precipitated depends on plasma chondromucoprotein concentration, while their composition and biological activities, notably their content of plasminogen and peroxidase-active methaemalbumin<sup>5</sup>, are a function of plasma pH.

Nucleic acids and other anionic polyelectrolytes also interact electrostatically with cationic plasma proteins<sup>6</sup>, and euglobulins precipitated at low ionic strength at certain pH values contain protein-protein complexes formed, for example, following interaction between basic  $\gamma$ -globulins and acidic  $\alpha$ - and  $\beta$ -globulins<sup>7</sup>. Chondromucoprotein, however, is of special interest since, unlike other plasma proteins, it is strongly anionic over a wide pH range. It is also the naturally occurring form of connective tissue chondroitin sulphate, the blood and urine

concentration of which is raised in certain diseases and in rabbits rendered chondrolytic by papain and plasminogen injections<sup>8</sup>.

However, protein fractions precipitating from plasma following dialysis or salting-out procedures are also termed 'euglobulins', and the following experiments were carried out to determine whether the composition of these fractions was also affected by chondromucoprotein.

**Euglobulins precipitated by dialysis of plasma against water at neutrality.** Euglobulins precipitated from normal plasma by this method contain globulins insoluble at low ionic strength near their isoelectric points<sup>9</sup>, in addition to complexes formed by interaction of  $\gamma$ -globulins, positively charged above pH 6.5, with acidic  $\alpha$ - and  $\beta$ -globulins<sup>7</sup>.

Human plasma (2 ml.) and 0.9 per cent sodium chloride (1 ml.) were measured into two tubes (A and B). Into tube A was added 0.9 per cent sodium chloride (0.67 ml.) and into tube B was added chondromucoprotein dissolved in 0.9 per cent sodium chloride (0.67 ml., prepared as described elsewhere<sup>4</sup>, and containing 1.9 mg of chondromucoprotein expressed as chondroitin sulphate). Each mixture was dialysed in air-tight vessels for 5 days against 15 changes of distilled water from which dissolved atmospheric carbon dioxide had previously been expelled by vigorous boiling. The final plasma pH was 7.0. The precipitated euglobulins were measured turbidimetrically at 400 m $\mu$  in a Unicam spectrophotometer (SP 500) in cells of 1 cm light path, extinction values for mixtures A and B being 0.294 and 0.070 respectively.

These results indicate diminished euglobulin precipitation at high chondromucoprotein concentration. The reason for this is obscure, but may be related to a protective colloid effect exerted by chondromucoprotein, a property shared by other mucosubstances<sup>10</sup>.

**Euglobulins precipitated by dialysis of plasma against water containing dissolved atmospheric carbon dioxide.** Plasma was dialysed against distilled water from which dissolved atmospheric carbon dioxide had not been removed by boiling. Under these conditions the plasma pH fell to 5.3. Euglobulin formation, assessed by measurements of protein, lipoproteins (as cholesterol), clottable fibrinogen and sialoproteins (as sialic acid) in the precipitates, was increased in the presence of added chondromucoprotein as shown in Fig. 1, an effect observed previ-

Fig. 1. Effect of chondromucoprotein on the spontaneous precipitation of euglobulins from dialysed plasma. Portions of human plasma (1.8 ml.) were measured into five tubes (1-5). To tube 1 was added 1.3 ml. of 0.9 per cent sodium chloride. To tubes 2-5 were added varying amounts of chondromucoprotein (0.17-1.7 mg, expressed as chondroitin sulphate) dissolved in 1.3 ml. of 0.9 per cent sodium chloride, the resulting plasma chondromucoprotein concentrations, in terms of chondroitin sulphate, ranging from 9.4 to 94 mg/100 ml. Each mixture was dialysed against 15 changes of distilled water at 4° for 5 days, after which time the plasma pH had fallen to 5.3. The precipitated euglobulins were centrifuged down, washed with acetate buffer (0.1 M, pH 5.3), dissolved in 2 ml. of phosphate buffer (0.1 M, pH 8.0) and the euglobulin solutions estimated for protein, sialic acid, clottable fibrinogen and cholesterol. These values are indicated by  $\circ$ ,  $\bullet$ ,  $\Delta$  and  $\blacktriangle$ , respectively.

ously in euglobulins precipitated from diluted plasma by the direct addition of acid<sup>2-4</sup>.

**Euglobulins precipitated from plasma by neutral salts.** Euglobulins were precipitated from plasma by adding sodium chloride or ammonium sulphate to 100 or 33 per cent saturation respectively. The amount and composition of these fractions, which contained fibrinogen and  $\gamma$ -globulins<sup>5</sup>, were unaffected by variable plasma chondromucoprotein concentration.

It is postulated that fractions precipitated from acidified plasma, whether by direct addition of acid or by dialysis of plasma against distilled water containing dissolved atmospheric carbon dioxide, contain insoluble complexes formed by electrostatic interaction between anionic chondromucoprotein and those plasma proteins cationic at pH values below their isoelectric points, their composition and biological activities depending on the precipitating pH. In conformity with these conclusions, euglobulins precipitated on dilution and acidification of plasma collected from rabbits after papain injection, when the plasma chondromucoprotein concentration as a result of chondrolysis can be raised some 100-fold, are considerably bulkier than those precipitated from normal rabbit plasma<sup>4</sup>.

Euglobulins precipitated from neutral plasma, on the other hand, whether by salt fractionation or by dialysis against distilled water free of carbon dioxide, were not increased in amount in the presence of added chondromucoprotein. This result was expected since at neutrality most of the plasma proteins were negatively charged and therefore unavailable for electrostatic interaction with chondromucoprotein<sup>2,4</sup>.

It is evident that, in addition to the complex mechanisms known to be involved in the aetiology of euglobulins precipitated from diluted acidified plasma, electrostatic interactions must be added, involving chondromucoprotein, the presence of which profoundly affects the amount precipitated, their composition and their biological activities.

## Labelling Rates and Detection of Intermediates in Mitochondrial Phosphorylations and other Sequential Reactions

Use of isotopes frequently provides a sensitive tool for detection of small concentrations of intermediates in metabolic sequences. Valuable information about the possible participation of an intermediate may often be obtained by measurement of rates of appearance of isotopic tracer in a possible intermediate and in a subsequent metabolic product. Such approaches have recently been applied to the assessment of possible phosphorylated intermediates in the formation of ATP by mitochondria, but important differences in the interpretation of the results have arisen<sup>1-3</sup>.

Slater *et al.*<sup>1</sup> expressed the view that the rate of labelling of any intermediate must equal or exceed the maximal rate of labelling of the product. In contrast, Bieber *et al.*<sup>2</sup>

Fig. 1

felt that such a criterion was not applicable to many plausible metabolic situations. Later, Slater and Kemp<sup>3</sup> objected to the interpretations of Bieber *et al.*<sup>2</sup>. Although other items were also presented by Slater and Kemp<sup>3</sup>, they appropriately emphasized that: "The point under discussion is the validity of kinetic criteria for distinguishing between possible reaction pathways in mitochondria." It is toward this point that this communication is directed, in particular to a further assessment of the criterion previously expressed<sup>1</sup> and recently re-stated<sup>3</sup> as: "We wish to reaffirm our view that the criterion that a given compound is an intermediate in oxidative phosphorylation should be that the initial rate of its labelling from <sup>32</sup>P<sub>i</sub> should not be less than the maximal rate of labelling of the product." They assume that the initial rate will be the maximal rate of labelling of an intermediate, an assumption which will hold only under certain conditions. As will be demonstrated here, however, the criterion suggested by Slater *et al.*<sup>1,3</sup> is invalid because either the initial or the maximal rate of labelling of an intermediate in metabolically plausible sequences may be far less than the maximal rate of labelling of the product. Clarification of this point is desirable because an understanding of the essential features of possible labelling patterns of metabolically active intermediates present in low concentration has considerable applicability not only to mitochondrial phosphorylations but also to many other sequential reactions.

As an appropriate system to demonstrate the lack of applicability of the criterion suggested by Slater and Kemp<sup>3</sup> to a reaction intermediate, a sequence of reactions which might logically occur in mitochondrial phosphorylations may be considered. This sequence is one in which <sup>32</sup>P<sub>i</sub> from the reaction medium first enters a pool of intramitochondrial P<sub>i</sub>, thence passes through an intermediate, present in much smaller amount than the intramitochondrial P<sub>i</sub>, to form ATP. Such a system is indicated schematically in Fig. 1. Only unidirectional reactions need be considered because even such a simple system suffices for mathematical demonstration that the initial or the maximal rate of labelling of an intermediate may be considerably less than maximal rate of labelling of the product.

The point to be demonstrated for the scheme depicted in Fig. 1 is that the rate of appearance of tracer, added as P<sub>0</sub>, in the intermediate, P<sub>2</sub>, at any time will be considerably less than the maximal rate of appearance of tracer in the product, P<sub>3</sub>. For derivation of the relationships governing such a system, let the amount of radioactivity present in the various pools be C<sub>0</sub>, C<sub>1</sub>, C<sub>2</sub>, and C<sub>3</sub>, respectively, and the rate of formation of P<sub>3</sub> = r. Assume that synthesis of P<sub>3</sub> is proceeding at a constant rate, and that a trace of isotope is added to P<sub>0</sub>, with a resultant specific activity of C<sub>0</sub>/P<sub>0</sub>. Then for appearance of isotope in C<sub>1</sub>, the appropriate relationship is:

$$\frac{dC_1}{dt} = \frac{C_0 r}{P_0} - \frac{r C_1}{P_1} \quad (1)$$

which on integration gives:

$$C_1 = \frac{C_0 P_1}{P_0} (1 - e^{-rt/P_1}) \quad (2)$$

For the appearance of radioactivity in C<sub>2</sub>:

$$\frac{dC_2}{dt} = \frac{C_1 r}{P_1} - \frac{r C_2}{P_2} \quad (3)$$

Substituting from equation (2) into (3) and integrating gives:

$$C_2 = \frac{C_0 P_2}{P_1} \left( \frac{1 - P_1 e^{-rt/P_1} - P_2 e^{-rt/P_2}}{P_1 - P_2} \right) \quad (4)$$

For the appearance of radioactivity in  $C_2$ :

$$\frac{dC_2}{dt} = \frac{C_2 r}{P_2} \quad (5)$$

Substituting from equation (4) into (5) and integrating gives:

$$C_2 = \frac{C_0}{P_1} \left( rt + \frac{P_1^2 e^{-rt/P_1} - P_1^2 e^{-rt/P_2}}{P_1 - P_2} - P_2 - P_1 \right) \quad (6)$$

Alternatively, in a system in which the  $P_1$  pool is lacking, so that the sequence is simply  $P_0 \rightarrow P_2 \rightarrow P_3$ , the appearance of label in  $P_2$  would be given by the relationship:

$$C_2 = \frac{C_0 P_2}{P_0} (1 - e^{-rt/P_2}) \quad (7)$$

and the appearance in  $P_3$  by the relationship:

$$C_3 = \frac{C_0}{P_0} (rt - P_2 + P_2 e^{-rt/P_2}) \quad (8)$$

To demonstrate the relative labelling rates which might ensue in such a system, assume that  $r = 1$  (for example, 1  $\mu$ mole of ATP being formed per second),  $P_1 = 10 \mu$ moles,  $P_2 = 0.1 \mu$ mole, and  $C_0/P_0$ , after addition of isotope = 1 (for example, 1  $\mu$ curie of  $^{32}$ P per  $\mu$ mole). Calculations from equations (2), (4), and (8) give labelling patterns as illustrated in Fig. 2A. Note that the curve for  $C_2$  is multiplied by 50, and thus that the maximal rate of appearance in isotope into  $P_2$  far exceeds the maximal rate of appearance into the intermediate,  $P_3$ . Only at the very outset, where the rates and the extent of labelling of both  $P_2$  and  $P_3$  are very small, and thus would not be experimentally rate of appearance of label in the intermediate exceed the rate of appearance into product.

If the pool  $P_1$  were not present, the labelling of  $P_2$  and  $P_3$ , as calculated from equations (6) and (7), would be as measurable in most circumstances, does the actual illustrated in Fig. 2B. As contrasted to the situation when  $P_1$  participates, of particular importance is the expected rapid initial rate of labelling of  $P_2$  and the very small lag in the labelling rate of  $P_3$ . Such a system, in which  $P_2$  is formed directly from  $P_0$ , and  $P_3$  does not equilibrate with any other pool, fits the labelling pattern visualized by Slater and Kemp<sup>3</sup>, namely, the initial rate of labelling of the intermediate as the maximal rate and equal to the maximal rate of labelling of product.

In both systems depicted by Fig. 2A and Fig. 2B, the labelling of  $P_2$  meets a quite separate criterion previously

suggested by Bieber *et al.*<sup>2</sup> for an intermediate, namely, that an intermediate should approach maximal labelling as soon as or before the maximal rate of labelling of ATP occurs. Plots of percentage of maximal labelling, contrary to the suggestion of Slater and Kemp<sup>3</sup>, can thus be quite useful.

The disparity in labelling rates for  $P_2$  and  $P_3$  in a system as depicted by Fig. 1 can be readily quantitated for the values used in calculating the curves of Fig. 2A. The rate of labelling of  $C_2$  is given by the derivatives of equation (4), which is:

$$\frac{dC_2}{dt} = \frac{C_0 P_2 r}{P_1 (P_1 - P_2)} (e^{-rt/P_2} - e^{-rt/P_1}) \quad (9)$$

The time at which maximal rate of labelling of  $C_2$  occurs corresponds to that at which the second derivative of equation 4 equals 0. The appropriate relationship is:

$$\frac{d^2 C_2}{dt^2} = \frac{C_0 P_2 r^2}{P_1 (P_1 - P_2)} \left( \frac{e^{-rt/P_2}}{P_2} - \frac{e^{-rt/P_1}}{P_1} \right) \quad (10)$$

For conditions as in Fig. 2A, this derivative equals zero at  $t = 0.48$  sec, and the maximal labelling rate of  $C_2$  may be calculated from equation (8) to be 0.0096 units of radioactivity per second, whereas the maximal rate of  $P_2$  (ATP) labelling is  $r C_0/P_0$ , or 1. Thus even though  $P_2$  is an intermediate in  $P_3$  formation, the maximal rate of labelling of  $P_2$  would be only 0.96 per cent that of  $P_3$  in the reasonable model under discussion. Slater, Kemp, and Tager<sup>1</sup> observed that the maximal rate of labelling of bound phosphohistidine in mitochondria was 1.5 per cent of the rate of labelling of ATP. Clearly on this basis alone and as pointed out by Bieber *et al.*<sup>2</sup>, bound phosphohistidine cannot be excluded as an intermediate in formation of most of the mitochondrial ATP.

The important contributing factors to a slow labelling of the intermediate  $P_2$ , as compared to the labelling of  $P_3$  (ATP) from  $^{32}$ P<sub>i</sub> in the scheme of Fig. 1, are the participation of the relatively large pool,  $P_1$ , as a precursor to  $P_2$ , and the small size and rapid turnover of  $P_1$ . The latter features are quite plausible for any intermediate in oxidative phosphorylation. The occurrence of a lag in the labelling of ATP, well-demonstrated by the results of Slater *et al.*<sup>1</sup> and of Bieber *et al.*<sup>2</sup>, gives strong evidence for the existence of a pool of considerable size through which  $^{32}$ P<sub>i</sub> must pass or with which  $P_1$  may equilibrate during the synthesis of ATP. The extent of any lag is an obvious function of the size of this pool. This is illustrated by the very small lag in ATP labelling exhibited when the synthesis of ATP is considered to involve only the small amount of  $P_2$  as an intermediate (Fig. 2B), as compared with the participation of an appreciable pool (Fig. 2A). As mentioned previously, lag in  $P_2$  (ATP) labelling and a slow rate of  $P_3$  labelling would also result if  $P_1$  were a pool which rapidly equilibrated with  $P_2$ , rather than serving as a precursor. In such a case, no lag would be observed with labelling of the intermediate.

The model system used in this communication to illustrate the limitations of the labelling data considers only a net flux of reactants in one direction, homogeneity of the reactant pools, and lack of other pools which the reactants equilibrate with or pass through. Much more complex relationships might exist in mitochondria, and labelling patterns with flux in both directions could be assessed by tracer methodology as elegantly discussed by Sheppard<sup>4</sup>. Increasing complexity of systems would not relieve the limitations of the simple model, and could introduce additional limitations.

The discussion of labelling patterns of intermediates is an outgrowth of experiments on

Fig. 2

the metabolic role of bound phosphohistidine<sup>1,2</sup>, and earlier suggestions from this laboratory that phosphohistidine appeared to be an intermediate in oxidative phosphorylation. The most definitive information about the metabolic role of this substance in mitochondria has come, not from measurements of labelling rates, but from observations of the close association of bound phosphohistidine with succinate thiokinase<sup>3,4</sup>. Much or all of the bound phosphohistidine of mitochondria may participate in the succinate thiokinase reaction, but participation of some of the phosphohistidine in other mitochondrial processes remains a distinct possibility<sup>5</sup>.

In summary, in sequential reactions from an initial reactant to a product, with addition of isotopic tracer to the reactant, a compulsory intermediate may show a much smaller maximal rate of labelling than the product. This is the case when the intermediate is present in small concentrations, has a rapid turnover, and is formed from a pool or substance of higher concentration initially labelled by the reactant. Similar considerations would hold if the intermediate were formed directly from the reactant but equilibrated with the other pool or substance before forming product. As applied to mitochondrial oxidative phosphorylations, this means that a phosphorylated intermediate might show a much slower rate of labelling from <sup>32</sup>Pi than does ATP.

BASED on his observation that mitochondrial protein-bound phosphohistidine becomes maximally labelled with added radioactive inorganic phosphate before maximum labelling of the mitochondrial ATP is reached, Prof. Boyer concluded in 1963 that protein-bound phosphohistidine is an intermediate in respiratory-chain phosphorylation<sup>1</sup>. By the summer of 1964, it was generally accepted that phosphohistidine is not on the main pathway of synthesis of mitochondrial ATP, but on the relatively slow side-path catalysed by succinyl-CoA synthetase and nucleosidediphosphate kinase. We had already pointed out early in 1964 that the kinetics of the incorporation were inconsistent with Boyer's theory and supported phosphohistidine as an intermediate on a slow side-path<sup>2</sup>.

What are the lessons to be drawn from this experience? Our conclusion is that the criterion for an intermediate of respiratory-chain phosphorylation used by Prof. Boyer is insufficient and that the more rigorous criterion emphasized in our recent communication<sup>3</sup> should be adopted. This is that the initial rate of labelling of the proposed intermediate should not be less than the maximal rate of labelling of the ATP. Prof. Boyer now states that there are circumstances in which the maximal rate of labelling of the intermediate could be very much less than the maximal rate of labelling of the ATP.

I accept that, under the conditions specified by Prof. Boyer, this would be the case. However, I do not agree that these conditions are likely to apply. In the model  $P_0 \rightarrow P_1 \rightarrow P_2 \rightarrow P_3$ , the transformation  $P_0 \rightarrow P_1$  represents the mixing of the medium inorganic phosphate with intramitochondrial inorganic phosphate, which is of

quite a different character from the chemical transformations  $P_1 \rightarrow P_2$  and  $P_2 \rightarrow P_3$ . There is an important implication buried in the assumption that, immediately after adding radioactive inorganic phosphate, the rates of all transformations would be the same. This would only be the case if the rate-limiting step of oxidative phosphorylation (or of the inorganic phosphate-ATP exchange reaction) were the penetration of added inorganic phosphate into a mitochondrial pool of inorganic phosphate. Is this likely? Is it not more likely that the rate of the transformation  $P_0 \rightarrow P_1$  will be greater than that of the other transformations, and that  $P_2$ , and therefore  $C_2$ , will rapidly decrease immediately after adding the radioactive phosphate? If this is the case, the mathematical treatments leading to equations 1, 2, 4 and 6 would be invalid.

The linear kinetics of labelling of phosphohistidine up to almost maximum labelling, previously reported (Fig. 2, ref. 2), shows that this labelling does not follow the model proposed by Prof. Boyer. The initial rate of labelling may be accurately calculated. Thus, the simpler assumption, which we made, namely that the mixing of added inorganic phosphate with a pool of mitochondrial phosphate is not rate-limiting in phosphohistidine labelling, would appear to be justified.

Prof. Boyer<sup>4</sup> argues that the lag in ATP labelling which we found shows the existence of a pool of considerable size through which radioactive phosphate must pass during the synthesis of ATP. Whether or not this is the correct explanation of the lag, it would not cause an over-estimate of the ATP labelling and would not, therefore, affect our conclusion that the rate of labelling of the ATP was much greater than that of the phosphohistidine.

Everyone agrees that there is now no evidence that phosphohistidine is an intermediate of respiratory-chain phosphorylation. The only question at issue is: what criterion should we apply to the next claim, that a labelled phosphate component of mitochondria is the long-sought 'X~P' of oxidative phosphorylation? Prof. Boyer reiterates that his criterion is sufficient, and that a slow rate of labelling of the proposed X~P can be accounted for by the considerations which he brings forward. I fear that adopting this criterion alone might lead once again to an unfounded claim. I suggest that, instead of explaining away a slow rate of labelling, conditions be sought in which these considerations do not apply, as is the case with phosphohistidine. For example, under some conditions there is no measurable lag in measuring the incorporation of radioactive phosphate into ATP, so that a "pool of considerable size" is not always present.

I agree that there are circumstances in which a phosphorylated intermediate might show a much slower rate of labelling from radioactive phosphate than does ATP. An example where we had to take this possibility into consideration comes from some recent work of Mr. A. Kemp, Jun., and Dr. R. B. Tobin in this laboratory. They found that, in the same experiment, the relative rates of labelling of phosphohistidine, Beyer's phosphoprotein<sup>4</sup> and ATP were 1.8:0.14:100. Since we have already excluded phosphohistidine as an intermediate, it might appear easy to exclude the still more slowly labelled Beyer phosphoprotein. However, there is a special feature of the labelling pattern in this case which precludes us from applying the same argument which we applied to the case of phosphohistidine. When the percentage of maximum labelling is plotted against time (Prof. Boyer's procedure), the curves for ATP and the Beyer protein fall on the same line. It is, in this case, possible that the rate of the reversible reaction  $X \sim P + ADP \rightleftharpoons X + ATP$  is so much faster than the rate of formation of X~P that the measured rate of incorporation of radioactive phosphate into X~P represents only the rate at which ATP reaches isotopic equilibrium, and nothing can be said about the rate of incorporation of inorganic phosphate into X~P. Thus, although Beyer's phosphoprotein fulfils Prof. Boyer's

criterion, I am not yet prepared to accept it as an intermediate of respiratory-chain phosphorylation. However, although it does not fulfil my criterion, a special circumstance does not allow us as yet to exclude it as an intermediate. Further experiments are required. Incidentally, there was no time lag of labelling of ATP in this experiment.

### Carbamyl Phosphate as an Essential Component of the Flattening Factor for Cells in Culture

A COMPOUND of low molecular weight which causes attachment and flattening of cells in culture was prepared from the growth-promoting  $\alpha$ -globulin<sup>1</sup>. The protein from which this low-molecular compound was isolated was prepared by chromatography on 'DEAE'-cellulose<sup>2</sup>; in further experiments it was found that this protein could be inactivated by filtration through 'Sephadex G-25'. Reactivation occurred after incubation of this protein with  $\text{NaH}_2\text{PO}_4$  or with  $\text{NaHCO}_3$ ; if not incubated with salts, the protein caused flattening of cells in 4–8 h, so that the process of flattening was prolonged.

These findings suggested that the active factor contained a compound of low molecular weight, capable of binding an inorganic salt. For this reason, the active protein was chromatographed in a butanol-acetic acid-water mixture (4:1:5) without deproteinization. Staining with bromocresol green disclosed two components,  $R_F$  0.08 yellow and  $R_F$  0.18 blue; this active system also contained a protein which remained at the starting spot. On chromatograms treated with ninhydrin one-colour reaction only was obtained. The same  $R_F$ -values and the same reactions were obtained with carbamyl phosphate prepared according to the method of Spector, Jones and Lippman<sup>3</sup>.

To investigate the significance of carbamyl phosphate for cultivation, HeLa cells were used. The cells were incubated in a synthetic medium<sup>4</sup> containing carbamyl phosphate in a concentration of 20–200  $\mu\text{g}$  per ml. At 37° C the cells attached to glass within 1 h and within 20 h they were all flattened, but they did not flatten as well as in a medium with  $\alpha$ -globulin. It was further observed that on supplementation of this synthetic medium with insulin the cells flattened well.

These results were not unexpected, because the crystalline carbamyl phosphate prepared by direct crystallization from the active protein behaves in the same way. In contrast to the crystalline carbamyl phosphate, a low-molecular compound prepared from the same protein after incubation with erythrocytes, and causing a flattening of cells to the same extent as the growth-promoting  $\alpha$ -globulin, contained at least ten amino-acids in acid hydrolysate<sup>4</sup>.

### Decomposition of Benzhydrol catalysed by Boric Acid

In a recent investigation of the secondary decomposition mechanisms in the pyrolysis of esters, it was discovered that the borate of benzyl alcohol decomposes to anthracene and resinous substances<sup>1</sup>. This result supports the contention of Chapman and Borden<sup>2</sup> that the elimination involves an ionic mechanism.

In an attempt to extend the synthetic capabilities of this reaction, the pyrolysis of benzhydrol was undertaken. The pyrolysis was conducted in the usual manner: the alcohol (1.84 g, 0.01 m) and boric acid (0.62 g, 0.01 m) were mixed in a 'Pyrex' tube and slowly heated to 140°. After 2 h the temperature of the heating bath was slowly raised to 280°–290°. Decomposition was complete after 1 h. The crude products were then dissolved in benzene and chromatographed on alumina. Elution with benzene-petroleum ether gave three products; benzophenone (0.133 g), diphenylmethane (0.085 g) and *s*-tetraphenylethane (0.248 g). Neither 9,10-diphenylanthracene nor other fluorescent derivatives were located.

To explain the different pyrolytic routes of benzhydrol and benzyl alcohol, it was suggested that benzhydrol may have undergone ether formation rather than the expected borate ester formation as in the case of benzyl alcohol. This explanation is reasonable, since benzhydrol ether does give rise to these products under thermal conditions<sup>3,4</sup>, and, theoretically, the rate of ether formation in the benzhydrol reaction would be expected to be faster than benzyl ether formation, since the activation energy required for the formation of diphenylmethyl carbonium ion would be lower than the energy required for the benzyl cation. In an attempt to support this concept, the pyrolysis was repeated; however, in this experiment the degradation was conducted only at the lower temperature for 2 h. At the end of this time, the contents of the tube were cooled and then extracted with ether. On evaporation of the solvent, crystals of benzhydrol ether (1.50 g, 85 per cent) were deposited. The compound was identified by infra-red analysis and mixed melting point determinations.

Under these conditions, therefore, the pyrolysis of benzhydrol appears to involve the formation of benzhydrol ether, and the final products are produced from the decomposition of this intermediate.

### Pregnant Mare Serum Gonadotrophin Potency: Effect of Single and Multiple Injections

It has been demonstrated that a single subcutaneous injection of pregnant mare serum gonadotrophin (PMSG) is as effective as multiple injections of the same amount of PMSG on the weight increase of the immature rat ovary<sup>1,2</sup>. However, it was later shown that multiple injections of PMSG were more effective in producing an increase in testis weight of three-day-old cockerels than a single injection of the gonadotrophin<sup>3</sup>. Because of these opposing views, it was of interest to re-investigate the chick testis response with a more sensitive assay method.

An assay was developed that made use of the incorporation of inorganic phosphorus-32 into testes of two-day-old cockerels as the end-point for gonadotrophin activity<sup>4</sup>. The phosphorus-32 end-point was more sensitive than gonad weight change, and the incorporation of this isotope

was linear for the log-dose response line with  $\mu$ g quantities of follicle-stimulating hormone and interstitial-cell-stimulating hormone. In addition, it has been shown that the uptake of phosphorus-32 is also linear with the log-dose of PMSG treatment between 0.025 and 20.00 International Units (I.U.)<sup>6</sup>. The PMSG-chick testis response was re-investigated by the phosphorus-32 assay method, rather than gonad weight change, because of the greater sensitivity of the isotopic end-point.

In Tables 1 and 2 the uptakes of phosphorus-32 by testes in chicks which received a single hormone injection 36 h before autopsy are compared with the uptakes by testes in chicks which received the hormone in 3 injections 36, 24, and 12 h before autopsy. Both experiments indicated that greater testicular stimulation (measured by incorporation of phosphorus-32) occurred with the single PMSG injection. The two experiments cannot truly be compared because the quantity of phosphorus-32 injected into the assay chicks was not the same for both experiments; however, it can be noted that increasing amounts of PMSG caused an increased uptake of phosphorus-32. The phosphorus-32 incorporation was linear when related to the log-dose of PMSG for both experiments.

The data in Table 1 indicate that small quantities of serum gonadotrophin (0.025 I.U.) could be assayed with this phosphorus-32 method. The slope of the phosphorus-32 c.p.m./mg log-dose response line was 33.54, and the percentage increases showed good differential responses with the various treatments. With all treatments, the effectiveness of the PMSG, measured by the incorporation of phosphorus-32, was much greater when administered as a single injection. These data were analysed by a balanced factorial analysis<sup>7</sup>. The results indicated that the standard treatments (single injection) differed significantly from the unknown treatments (multiple injections), but both log-dose response lines were parallel. This response

indicated that these preparations differed only in potency, and therefore the relative potency of the unknown treatments was calculated. It was found that PMSG, administered in three injections, was only 59.9 per cent as potent as the same amount of hormone given in a single injection.

To determine if this type of response could be duplicated, another experiment, using slightly greater concentrations of PMSG, was performed. These data are presented in Table 2, and the results are similar to those of the previous experiment. The single PMSG injection caused a much greater incorporation of phosphorus-32 than did the same amount of gonadotrophin administered in three injections. The relative potency was calculated, and it was found that the multiple injections of PMSG were only 48.7 per cent as potent as the single gonadotrophin injections.

These results support the earlier observations which indicated that a single PMSG injection was as effective as were multiple injections. The explanation for this phenomenon is that the molecular size of PMSG, 68,000 (ref. 7), is too large to be cleared by the kidney, and consequently, it remains in the circulation until utilized or degraded. This explanation would seem at present to be the best one for this phenomenon.

### Creatine Phosphokinase Isoenzymes

CREATINE phosphokinase (adenosine triphosphate: creatine phosphotransferase) has been shown by electrophoretic separation on agar gel and starch gel to exist in multiple molecular forms (isoenzymes)<sup>1-3</sup>. This communication describes a staining technique for creatine phosphokinase (CPK) and its application to the demonstration of CPK isoenzymes separated on cellulose acetate membranes.

Tissue homogenates and sera (5  $\mu$ l.) are separated on cellulose acetate membranes<sup>4</sup> in barbitone buffer pH 8.6, using a constant current of 0.5 m. amp/cm for 1.25 h. A staining solution the composition of which is based on Oliver's method for CPK determination<sup>5,6</sup> is prepared as follows:

Adenosine-5-diphosphate sodium salt (C. F. Boehringer and Son), 2 mg; hexokinase (C. F. Boehringer and Son), 10  $\mu$ l. (2.8 i.u.); glucose-6-phosphate dehydrogenase (C. F. Boehringer and Son), 10  $\mu$ l. (1.4 i.u.); glucose, 2 mg; magnesium sulphate ( $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ), 7 mg; nicotinamide adenine dinucleotide phosphate (NADP, or TPN; C. F. Boehringer and Son), 3 mg; MTT (3-(4,5-dimethylthiazolyl-2)-2,5-diphenyl tetrazolium bromide; (George T. Gurr, Ltd.), 1.6 mg 0.05 M tris buffer pH 7.5, 3 ml.

This solution is divided into equal parts, and 5 mg creatine phosphate (C. F. Boehringer and Son) added to half to constitute the test solution, the remaining half serving as a control solution. Immediately prior to use, 80  $\mu$ l. of phenazine methosulphate (*N*-methyl-phenazonium methosulphate; British Drug Houses, Ltd.), freshly dissolved in distilled water at a concentration of 1 mg/ml., are added to both test and control.

Following electrophoretic separation, the cellulose acetate is divided longitudinally, and one half-strip is stained for CPK activity using the test solution. The remaining half-strip is stained with the control solution. For staining, a layering technique is used<sup>7</sup>, the half-strip being layered on to an additional cellulose acetate strip which has been allowed to soak up staining solution. Both strips are incubated in a moist chamber for 1 h at 37° C.

Fig. 1 illustrates the results obtained by the examination of adult human muscle homogenates. Muscle was homogenized at a concentration of 50–100 mg wet weight of tissue per ml. in distilled water, using a Potter-Elvehjem homogenizer. The homogenate was lightly centrifuged (2,000 r.p.m.) for 10 min, and the supernatant diluted with distilled water to yield a CPK activity of approximately 2,000–4,000 i.u. per litre by Hughes's method<sup>8</sup>. Two sera of activities 5,500 and 3,900 i.u. per litre, from patients with muscular dystrophy of Duchenne type (kindly supplied by Dr. B. P. Hughes of the National Hospital, London), were also examined.

Cardiac muscle showed a major staining band with a mobility intermediate between that of serum  $\beta$ - and  $\gamma$ -globulins. A minor component with a mobility of that of an  $\alpha$ -2 globulin was also demonstrable. No staining of

the control strips was observed. A similar isoenzyme pattern was obtained with three specimens of skeletal muscle shown by histochemical and biochemical means to be composed chiefly of 'red' muscle fibres<sup>9</sup>. Three specimens of skeletal muscle similarly shown to be composed chiefly of 'white' muscle fibres showed only the major isoenzyme band. The sera from the two patients with muscular dystrophy showed only the major component.

### Effect of Urea on the Cold Precipitation of Protein in the Lens of the Dogfish

WHEN lenses of young rats are cooled below 10° C they become reversibly opaque due to the precipitation of a cold-precipitable protein. This fraction is prepared by homogenizing rat lenses in several volumes of water and cooling the 105,000g supernatant to 0° C. Repeated solubilization at 20° C and precipitation at 0° C serves as a means of purification<sup>1</sup>. The cold-precipitation phenomenon is thought to be caused by changes in protein conformation due to a disturbance of the balance between hydrogen and hydrophobic bonding of protein chains at lower temperatures.

Purified rat lens cold-precipitable protein was found to be homogeneous in the analytical ultracentrifuge (with a 4s sedimentation rate at 20° C), but was shown to be heterogeneous by means of acrylamide gel electrophoresis, agar-plate immunodiffusion, and 'Sephadex G-100' gel filtration investigations<sup>2</sup>. Cold-precipitable protein was found to contain species similar to the  $\alpha$ -,  $\beta$ - and  $\gamma$ -crystallin protein fractions of the lens. Cold precipitation was dependent on the concentration of protein, the ionic strength and the pH of the solution containing cold-precipitable protein.

Further work indicated that a urea level of 0.25–0.3 M tended to inhibit the phenomenon of cold precipitation<sup>3</sup>. This observation led to the present investigation of the effect of the relatively high tissue concentration of urea (0.25 M) on dogfish lens cold-precipitable protein.

Initial investigations demonstrated that intact dogfish (*Mustelus canis*) lenses did not become opaque on cooling. Preparation of the dogfish lens cold precipitable protein fraction therefore required extensive dialysis of the 105,000g supernatant against water in order to remove urea and thus to allow cold precipitation to occur. When 0.25 M urea was added back to a preparation of cold-precipitable protein, cold precipitation was prevented.

Dogfish lens cold-precipitable protein exhibits characteristics similar to that of the rat lens. It decreases in concentration as the animal ages from a level of 17 per cent of the total soluble protein in the young dogfish and 35 per cent in the foetal rat lens to 5–7 per cent in the lenses of older animals. In both species the cold-precipitable protein fraction contains 1.5 per cent (by weight) RNA. Ultracentrifugal analysis of the dogfish or rat lens cold-precipitable protein at 20° C (pH 8.0) reveals a single peak with a sedimentation rate of 4S as compared to the

Fig. 1. Creatine phosphokinase isoenzymes of muscle

Fig. 1

Fig. 2

Fig. 1. Schlieren patterns obtained with the Beckman-Spinco model B analytical ultracentrifuge for 1.5 per cent cold-soluble dogfish lens protein fraction (above) and for 1 per cent cold-precipitable protein (below) in water. The print was made 20 min after rotation at 56,100 r.p.m. at 20° C. The upper pattern represents the sedimentation of  $\alpha$ -,  $\beta$ - and  $\gamma$ -crystallins with  $S$  values of 19, 13 and 8. The peak in the lower pattern had a 4S rate.

Fig. 2. Effect of acid (pH 3.0) and lowered temperatures (4° C) on the ultracentrifugal pattern of 1 per cent cold-precipitable protein of the dogfish lens. The print was made 20 min after rotation at 56,100 r.p.m.  $S$  values of 13 and 8 were obtained for the first and second peaks respectively.

19S, 13S and 8S values of both rat and dogfish lens  $\alpha$ -,  $\beta$ - and  $\gamma$ -crystallins (Fig. 1). At 4° C and pH 3.0 the single peak is replaced by a minor 8S and a major 13S peak for the dogfish (Fig. 2) as compared with a 8S and 17S peak for the rat preparation.

Gel filtration of purified dogfish lens cold-precipitable protein on 'Sephadex G-100' columns in 0.025 M *tris* buffer (pH 7.4) separates two components as shown in Fig. 3. The first contains two species of lens protein similar in sedimentation rate to that of  $\alpha$ - and  $\beta$ -crystallins; the second peak contains a single species with a sedimentation rate similar to that of  $\gamma$ -crystallin. (The separation of beef lens soluble protein by 'Sephadex' gel filtration was first reported by Bjork<sup>4</sup>.) When the  $\alpha$ -crystallin-type components of the first peak were separated from the  $\beta$ -crystallin-type components (by isoelectric precipitation of the  $\alpha$ -crystallin at pH 5.0) and protein estimations (Lowry procedure) were done on the three sub-fractions,  $\alpha$ - and  $\beta$ -crystallins contributed approximately 20 per cent each and  $\gamma$ -crystallin the remainder.

The experiments so far show that the dogfish lens contains a cold-precipitable protein fraction similar in physical and chemical properties to that of mammalian lenses. They indicate further that 0.25–0.3 M urea can in some way affect the interactions between lens proteins in solution. Finally, it appears that the relatively high concentration of urea in the dogfish lens is a factor in maintaining the clarity of the lens at environmental temperatures below 10° C.

This work was supported by U.S. Public Health Service grant B-3081, Fight for Sight Fellowship (S. Z.), from the

Fig. 3. Elution pattern obtained by passing 20 mg of cold-precipitable protein in 0.5 ml. of 0.025 M *tris* (pH 7.4) buffer through a column of Sephadex G-100 (20 cm x 1.5 cm) suspended in 0.025 M *tris* (pH 7.4) buffer. Each fraction collected contained 1 ml. of elution fluid. The first peak represents  $\alpha$  and  $\beta$ -crystallin components, whereas the second represents  $\gamma$ -crystallin components of the cold-precipitable protein.

## PHYSIOLOGY

### Evaporative Cooling in the Pig

ALTHOUGH the pig has well-developed structures in the skin which conform morphologically with apocrine sweat glands, the animal does not appear to sweat. Measurements made by Moritz and Henriques<sup>1</sup> and Ingram<sup>2</sup> showed that at temperatures below the critical temperature, cutaneous water-loss over the general body surface, but excluding the snout, is similar to that in man and other animals. At high environment temperatures, however, even when body temperature is elevated, water-loss from pig skin is only of the order of 80 g/m<sup>2</sup> h and can be accounted for by the increased vapour pressure gradient consequent on the increase in skin temperature which occurs after vasodilatation. Confirmation of a low evaporative heat loss also derives from observation made on the new-born pig by Mount<sup>3</sup>, who estimated that the increased evaporative loss at high ambient temperatures could be accounted for by losses from the respiratory tract alone.

Under very humid conditions water passes into the skin of pigs from the atmosphere against the vapour pressure gradient<sup>4</sup>, as it does in man<sup>5,6</sup>, but while in man, who sweats, there is a net loss of water, in the pig there is a net gain<sup>4</sup>. As a result of this low evaporative loss, the pig is only slightly affected by changes in humidity and is not tolerant of high ambient temperatures<sup>4</sup>.

Under natural conditions, however, pigs wallow in any available mud or even their own urine and therefore achieve a greater evaporative loss than the above measurement would suggest. In order to obtain a measure of the effectiveness of this means of cooling, observations were made on the evaporative loss from the flank of the pig smeared with mud or made thoroughly wet with water. The rate of water-loss was measured by means of the ventilated capsule<sup>7</sup> used previously on the pig<sup>3,4</sup>.

The results of an experiment in which a pig was exposed to 35° C dry bulb and 21° C wet bulb, and water-loss was recorded continuously on a chart are displayed in Fig. 1. At first the capsule sampled room air (zero water-loss). It was then strapped on to the animal (A) to register an evaporative rate of 30–40 g/m<sup>2</sup> h. When mud was smeared over the flank of the animal (B) the evaporation rate increased rapidly to about 800 g/m<sup>2</sup> h, and remained at this level for more than 1 h. The dotted line in Fig. 1 indicates the rise in evaporation rate after soaking the flank with water. In both instances the evaporation rate rose quickly, but using water the rate soon declined again, while in the experiment using mud the control value had still not been reached after more than 2 h, when the capsule was again allowed to sample room air (C).

The behaviour of the pig thus transforms the animal from one in which evaporative heat loss is small (Table 1) to one in which the evaporation rate is comparable with that of man. Moreover, since the evaporative rate remains high for a long period after the application of mud, the

Fig. 1. Hypocutaneous water-loss from the skin of a pig measured by the ventilated capsule technique. At A the capsule was placed on the skin. At B mud (continuous line) or water (dotted line) was smeared over the skin. At C the capsule was removed from the skin surface.

Table 1. WATER-LOSS FROM THE SKIN OF VARIOUS SPECIES (g/m² h)

Species	Below 30°C dry bulb	Above 30°C dry bulb
Pig <sup>a</sup>	7-16	24-82
Sheep <sup>a</sup>	12	63
European cattle <sup>a</sup>	12-16	67-144
Man (at rest) <sup>10,11</sup>	6-10	150
Man (at work) <sup>12</sup>	—	1,200

animal is free to move some distance away from the mud wallow. Even sweating man must have access to water, but while man faces a problem of salt balance as a result of sodium chloride loss in the sweat, the pig avoids the problem. Its bristle coat probably helps to retain mud on the skin; moreover, in domestic pigs at least, the coat is too sparse to prevent contact with the skin, with the result that the evaporative cooling can be expected to cool the skin directly. If, on the other hand, the coat was thick and close, the mud might not be in contact with the skin and hence the efficiency of the cooling would be impaired.

Thus the pig, which at first appears to be unsuited to hot climates, has potentialities of high heat tolerance by virtue of its behaviour.

### Chronic Thiouracil Feeding and Accumulation of <sup>125</sup>I in some Organs of C<sub>3</sub>H Mice

For many years radioactive iodine has been used as an indicator of iodine metabolism by the thyroid gland. Compounds such as thyroxine, labelled with <sup>125</sup>I, have served not only for that purpose, but also to study the peripheral metabolism of thyroid hormones. Gross and Schwartz<sup>1</sup> and Corey and Gross<sup>2</sup> have found that radioactive thyroxine accumulates in the liver and mammary gland tumours of C<sub>3</sub>H mice.

Thiourea compounds such as thiouracil (TU) and propylthiouracil (PTU) have been valuable tools in clarifying thyroid physiology. There is abundant experimental evidence to show that these goitrogens exert a thyroidal effect by blocking the synthesis of the gland's secretions and also an extra-thyroidal action on the peripheral

metabolism of thyroxine. Escobar del Rey<sup>3</sup> in rats, and Slingerland and Burrows<sup>4</sup> in humans, have presented enough data to indicate that TU and PTU interfere with peripheral de-iodination of thyroid hormone(s).

The experiments performed with rats by most of these researchers were done in animals given the goitrogens for periods not exceeding a few weeks. In our chronic experiments with C<sub>3</sub>H mice fed 0.3 per cent TU diet for periods of more than 11 months we investigated the iodine accumulation by gastrocnemius muscle, liver and intestine, in the hope of finding some more evidence that would indicate the extra-thyroidal effect of this goitrogen on iodine metabolism.

Three experimental and 3 stock-fed control animals were injected with <sup>125</sup>I after 11 months on the TU dietary regimen. Another 3 experimental mice and 3 stock-fed controls were similarly injected 16 months after feeding TU. Each mouse received subcutaneously 33.6 µc. of carrier-free <sup>125</sup>I as NaI. The radioactivity of the organs was determined with a Geiger-Müller counter 24 h after injection. The tissue samples were washed with isotonic saline and, after being weighed and minced, were placed in small, stoppered glass bottles for radioactivity readings. The amount of <sup>125</sup>I recovered from each of the 3 organs studied is shown by Fig. 1.

An analysis of variance of the results revealed a statistically significant difference ( $P < 0.001$ ) in the <sup>125</sup>I retained 24 h after injection between the different organs of mice given TU. There was a significant difference between muscle and intestine, and muscle and liver, but not between intestine and liver. The increasing iodine retention was especially noticeable in liver and intestine.

A statistically significant difference was also found between the amount of <sup>125</sup>I retained by all organs in the control animals and in those given TU for 11 months and for 16 months. Likewise, the difference in the amount of <sup>125</sup>I in the organs after 11 months and after 16 months of treatment was significant.

The foregoing results showed that 24 h after injection of <sup>125</sup>I, C<sub>3</sub>H mice, chronically fed a 0.3 per cent thiouracil (TU) diet for 11 or 16 months, have a significantly increased retention of the <sup>125</sup>I in gastrocnemius muscle, intestine and liver when compared with control animals fed no goitrogen. This may represent a reduced utilization

Fig. 1. Graph showing percentage recovery of <sup>125</sup>I from muscle, intestine and liver. C, controls, 11, 11 months on TU, 16, 16 months on TU.

of iodinated compounds and/or a decrease in the rate of  $^{125}\text{I}$  excretion in this strain of mice treated with TU. The iodinated compounds may be in the form of thyroid secretion or in the form of unknown  $^{125}\text{I}$ -labelled material.

### Effect of Rifamycin on Protein Synthesis

In an earlier paper<sup>1</sup> we reported that rifamycins  $M_{14}$  (diethylamide of rifamycin B) and SV inhibited  $^{14}\text{C}$  L-isoleucine incorporation by cell-free extracts of *B. subtilis* strain ATCC 6633.

L-Isoleucine incorporation into protein was dependent on the addition of DNA to the reaction mixture, and the results of our experiments did not allow us to decide whether the inhibition of the incorporation of amino-acids, caused by rifamycin, was connected with an effect of the antibiotic on the synthesis of messenger RNA or with an inhibition of protein synthesis at the ribosome level; activation of amino-acids was not affected by rifamycins<sup>1</sup>.

We now report the effects of rifamycin  $M_{14}$  on  $^{14}\text{C}$  uracil incorporation into trichloroacetic acid (TCA)-insoluble material and on the *in vitro* incorporation of amino-acids into proteins in the presence of polyuridylic acid (poly U) and of high molecular weight RNA from *B. steierthermophilus*.

*B. subtilis* strain ATCC 6633 was cultivated and the extracts prepared as previously reported<sup>1</sup>. In all experiments of *in vitro* protein synthesis the supernatant of centrifugation at 80,000g (S-30) was prepared by the method reported by Matthaei and Nirenberg<sup>2</sup>.

Polyuridylic acid was a Mann product; stimulation of phenylalanine incorporation could be obtained only when

Table 1

Additions	C.p.m./mg protein	Percentage inhibition
Complete mixture	210	
Complete mixture + 0.03 $\mu\text{moles/ml}$ rifamycin $M_{14}$	210	
Complete mixture + 100 $\mu\text{g/ml}$ DNA	1,500

Complete mixture* + 0.03 $\mu\text{moles/ml}$ rifamycin $M_{14}$ + 80 $\mu\text{g/ml}$ poly U	1,050	84
Complete mixture† + 80 $\mu\text{g/ml}$ poly U + 0.03 $\mu\text{moles/ml}$ rifamycin $M_{14}$	2,670	40

The reaction mixture contained the following, in  $\mu\text{moles/ml}$ : 100 *tris*-HCl, pH 7.4; 13 magnesium acetate; 50 ammonium acetate; 6 mercaptoethanol; 1 ATP; 5 phosphoenolpyruvate; 20  $\mu\text{g/ml}$  pyruvate kinase; 0.05 each of 20 L-amino-acids minus L-phenylalanine; 0.03 GTP; 0.03  $^{14}\text{C}$  L-phenylalanine (specific activity  $74 \times 10^4$  c.p.m./ $\mu\text{mole}$ ); 2 mg/ml S-30 protein. Total volume was 250  $\mu\text{l}$ . Samples were incubated at 37° C for 45 min, and the reaction was stopped with perchloric acid by the method of Ofengand *et al.*<sup>3</sup>. Radioactivity was determined by a windowless gas-flow counter.

\* Rifamycin was incubated for 5 min at room temperature in the complete assay mixture before addition of poly U.

† Poly U was incubated for 5 min at room temperature in the complete assay mixture before addition of rifamycin.

Fig. 1. Effect of rifamycin on  $^{14}\text{C}$  uracil incorporation into TCA-insoluble material. Cells were grown in medium  $A_{K-2}$  (ref. 6) supplemented with 20  $\mu\text{g/ml}$  guanine, 20  $\mu\text{g/ml}$  cytosine, 10  $\mu\text{g/ml}$  uracil. When the culture had reached an optical density at 490 m $\mu$  of 0.150 the culture was chilled, and the cells were centrifuged and resuspended in 0.1 M phosphate buffer, pH 7, with the same supplements and containing 0.2 per cent glucose and 2  $\mu\text{g/ml}$   $^{14}\text{C}$  uracil (specific activity  $2.24 \times 10^5$  c.p.m./ $\mu\text{mole}$ ). The suspension was divided in 2 tubes, one tube also contained rifamycin  $M_{14}$  at a final concentration of 5  $\mu\text{g/ml}$ . At 5-min intervals portions were taken and, after an optical density reading at 490 m $\mu$ , were treated with 2 volumes 7.5 per cent TCA. Precipitates were centrifuged and washed 3 times with 5 per cent cold TCA and dissolved in 1.7 N  $\text{NH}_4\text{OH}$ , the radioactivity was determined by a windowless gas-flow counter. (O---O) C.p.m./ml. of culture into TCA-insoluble material in the presence of 5  $\mu\text{g/ml}$  rifamycin  $M_{14}$ ; (●—●) without rifamycin  $M_{14}$ ; ( $\Delta$ --- $\Delta$ ) O.D. at 490 m $\mu$  of culture in the presence of 5  $\mu\text{g/ml}$  rifamycin  $M_{14}$ ; ( $\Delta$ — $\Delta$ ) without rifamycin  $M_{14}$ .

this product was separated from fragments of low molecular weight by precipitation from a solution in 0.5 M KCl with half volume ethanol.

$^{14}\text{C}$  L-phenylalanine and  $^{14}\text{C}$  L-isoleucine were obtained from S.O.R.I.N. (Vercelli, Italy) and  $^{14}\text{C}$  uracil from the Radiochemical Centre, Amersham, Buckinghamshire.

RNA from *B. steierthermophilus* was a gift of Dr. M. Arca. This RNA contained only two components of 17 and 23 S as shown by ultracentrifuge sedimentation patterns<sup>4</sup>.

DNA was prepared following the method reported by Marmur<sup>5</sup>.

In Tables 1 and 2 the effect of rifamycin  $M_{14}$  on the incorporation into protein of  $^{14}\text{C}$  L-isoleucine and  $^{14}\text{C}$  L-phenylalanine in the presence of high molecular weight RNA and of poly U is reported.

To test the effect of rifamycin on RNA synthesis, the incorporation of  $^{14}\text{C}$ -uracil into nucleic acids was followed by the method described by Dubin *et al.*<sup>6</sup>. Results are reported in Fig. 1 as TCA-precipitable counts per ml. of culture. The same figure shows the optical density of the cultures.

Fig. 1 demonstrates a strong inhibition of uracil incorporation into TCA-precipitable material in the presence of rifamycin. This inhibition, however, cannot be considered as direct evidence in favour of an action of rifamycin on RNA synthesis since rifamycin might cause a decrease of cell permeability (a decrease of cell permeability might be connected with the inhibition by rifamycin of the oxidation of exogenous substrates<sup>7</sup>). Alternatively, the decrease of RNA synthesis might be a secondary effect of

For the intestinal transport of amino-acids, the carboxyl and amino-groups appear to be of key importance<sup>1</sup>. In the case of cystine, there has been suggestive evidence that the disulphide group might also play a part in the movement of the compound<sup>2,3</sup>. We present here simple but compelling data on the participation of the disulphide moiety in cystine transport. There is shown to be *in vitro* intestinal transport of cystine and homocystine against a concentration gradient, while 9 analogues which do not possess the —S—S— linkage are not transported.

L-Cystine-<sup>35</sup>S (Schwarz) had carrier added as necessary. Diaminopimelic acid in radiolabelled form was obtained from commercial suppliers (diaminopimelic acid-2,6-<sup>14</sup>C, Cal. Biochem., and the generally tritiated compound, Amersham Radiochemical Centre). L-Homocystine-<sup>35</sup>S

Results of the transport experiments are shown in Table 1. Cystine and homocystine were transported against a concentration gradient by the small intestine of the hamster. Within the limits of detection, none of the other analogues was transported. That is, replacing the —S—S— by other linkage groupings resulted in cessation of transport. Initial studies have also been performed utilizing everted intestinal sacs from the rat and mouse. Results in these species are so far identical with those in the hamster for the three compounds tested—transport of cystine but not of diaminopimelic acid or djenkolic acid. Results of the studies on possible inhibition of cystine transport by its analogues are shown in Table 2. None of the compounds, including the transported L-homocystine, inhibited L-cystine movement against a concentration gradient. Perhaps this is not too surprising; these compounds have limited solubility and, at the resulting low concentration, the transport system is probably not saturated.

was stated to represent interference, by the charge on the side-chain, with the transport system. The significance of this observation, and the relationship of the compound to cystine, were apparently not reported. A more recent paper, by Randall and Evers<sup>8</sup>, indicated that the small intestine of the rat did not transport diaminopimelic acid, at higher concentrations, against a concentration gradient.

Reasons for the transport of cystine and homocysteine, but not the analogues lacking the disulphide grouping, must centre about the presence of the —S—S— linkage in the first two materials. A conjectural possibility is that the transported moiety is cysteine, with its —SH— group. Small amounts of cysteine might be in equilibrium with cystine, or perhaps cysteine can be formed from the —S—S— compound by the action of the gut wall. Indeed, an abnormality of cystine-cysteine interrelations has been postulated in cystinuria<sup>9</sup>. The occurrence of the disulphide of cysteine and homocysteine in the urine of cystinuric individuals suggests an abnormal disulphide interchange<sup>9</sup>. One of the defects in cystinuria, or a result of the disease, may be an inability to cleave the —S—S— bond at the appropriate moment, leading to the eventual formation of inappropriate compounds. However, altered disulphide interchange or rotation of the groups at the —S—S— bond cannot be excluded at present.

We thank Barbara Lutters, Francis Vishno and Bunardy Evans for their assistance and Dr. K. McConnell and Dr. W. H. Gunther for their advice.

## PHARMACOLOGY

### Inhibition of a Brain Protease by General Anaesthetics

We described previously a protease in rat brain cortex the activity of which increased after electrical stimulation of afferent nerves<sup>1</sup>. Further investigations have shown that this enzyme, besides being active on the synthetic substrates N-acetyl-L-tryptophan ethyl ester (ATrEe) and N-acetyl-L-tyrosine ethyl ester (ATyEe), is also capable of hydrolysing casein and that it is activated by the addition of cysteine. Its optimum pH is 7.1. A similar enzyme was extracted from rat brain by Guroff<sup>2</sup>.

The activity of this protease was found to be modified by various drugs administered *in vivo*<sup>3</sup>. It was noted, particularly, that ether and chloroform prevented the increase of enzyme activity induced by stimulation of the brain. More recently a systematic study of drug action

on the brain protease was undertaken *in vitro*. This report deals with the effects of the following anaesthetic agents: diethyl ether (DEe), chloroform (CHCl<sub>3</sub>), trichloroethylene (Cl<sub>3</sub>Et), halothane (Hal), methoxyflurane (MeOF), ethylvinyl ether (EVe) and divinyl ether (DVe).

The protease was prepared by adding 20 vol. of cold acetone ( $-20^{\circ}$  C) to freshly collected rat brains. After homogenization in a Waring blender and stirring for 2 h at low temperature, the precipitate was collected. After drying, the precipitate was ground up in 0.15 M sodium chloride and extracted at room temperature for 6 h. After centrifugation, the enzymatic activity of the supernatant was 3–4  $\mu$ moles of ATyEe hydrolysed/h/g wet brain. Addition of  $5 \times 10^{-3}$  M cysteine increased the activity to 7–8  $\mu$ moles/h/g. Tyrosine released by hydrolysis of casein was estimated by the fluorometric method<sup>4</sup> which allows measurement of a few nmoles of the amino-acid. The enzyme released 150–200 nmoles of tyrosine/h/g tissue without cysteine and 500–700 nmoles/h/g in the presence of cysteine.

The anaesthetic agents were used in saturated aqueous solutions. Varying amounts of these solutions were incubated with the quantity of enzyme corresponding to 100 mg of brain,  $5 \times 10^{-3}$  M cysteine and 0.8 ml. of a 1 per cent casein solution at pH 7.1 (0.025 M Tris buffer), in a total volume of 2 ml. After 1 h at room temperature, the proteins were precipitated with trichloroacetic acid (final concentration 6 per cent) and tyrosine was estimated in the filtrate. An identical sample was treated with trichloroacetic acid at zero time and its filtrate was used as blank. Control samples were incubated without anaesthetics.

Table 1. PROTEASE INHIBITION AND ANAESTHETIC POTENCY

	ml. of sat. sol./ml.	IC <sub>50</sub> mg/ml.	AD <sub>50</sub> mg/ml. (20°)
Diethyl ether	0.287	20.00	2.16
Divinyl ether	2.500*	7.75	—
Ethylvinyl ether	0.594*	4.75	—
Trichloroethylene	0.225	1.40	—
Chloroform	0.054	1.07	0.167
Halothane	0.150	0.56	0.0758
Methoxyflurane	0.183	0.43	0.0675

\* Extrapolated values.

Each agent was tested at several concentrations and the concentration necessary to inhibit 50 per cent of the enzyme activity was determined. Table 1 shows the results in terms of ml. of the saturated solution, and in mg/ml., calculated from the solubility of the agent in water at 20° C and from its specific gravity. For DVe and EVe, which have low solubility and low inhibitory action, the 50 per cent inhibition had to be extrapolated.

The significance of these findings depends largely on the correlation between enzyme inhibition and anaesthetic potency. The literature contains few reliable data on the potency of general anaesthetics. The most accurate values have been published recently by Cherkin and Catchpool on DEe, CHCl<sub>3</sub>, Hal and MeOF, determined in goldfish<sup>5</sup>. Fig. 1 shows the correlation for these agents between the concentration required for 50 per cent protease inhibition (IC<sub>50</sub>) and the concentration which caused anaesthesia in 50 per cent of the goldfish (AD<sub>50</sub>). No accurate values are available for the other three anaesthetics, but DVe and EVe are believed to have an activity of the same order as DEe and Cl<sub>3</sub>Et, similar to that of CHCl<sub>3</sub>.

This remarkable correlation ( $r = 0.991 \pm 0.010$ ) would add one more to the many physical and chemical properties of the anaesthetic agents associated with their pharmacological activity. Protease inhibition can probably be understood best in the context of the recent work of Pauling<sup>6</sup> and Miller<sup>7</sup>, which points to a combination of anaesthetics with the structured water surrounding protein molecules. This combination would probably include protein side-chains<sup>8</sup> and, by involving active sites of enzymes, could result in their inhibition. My efforts are

Fig. 1. Correlation between enzyme inhibition and anaesthetic potency. Abscissa: enzyme concentration inhibiting 50 per cent of enzyme activity ( $IC_{50}$ ); ordinate: anaesthetic potency according to Oberkin and Catapool (ref. 5). Both on log scale. DEe, diethyl ether; Hal, halothane; MeOF, methoxyflurane.

now being directed towards the purification of the enzyme and the analysis of other drug actions on it. These investigations may supply further information on the functional significance of the enzyme and its possible role in anaesthetic action.

### Peri-renal Sarcoma Induced by Cellulose Wrapping

EXPERIMENTAL, perinephritic, renal hypertension may be produced by wrapping the kidneys in a variety of inert substances such as silk<sup>1,2</sup>, latex<sup>3</sup>, plastic solutions<sup>4</sup> and cellulose material<sup>5</sup>.

An attempt was made to produce hypertension in Wistar rats by wrapping the kidneys with 'Viaking' dialysis tubing (manufactured by Hudec Merchandising Corporation). This was abandoned in favour of unilateral renal artery clipping with contralateral nephrectomy; the majority of animals being killed. Four animals survived for 9 months, but were then killed because of abdominal swelling causing respiratory distress. Post-mortem examination revealed bilateral, firm, white tumour masses enclosing both kidneys in all animals and in one case (Fig. 1) invading the renal parenchyma. Two out of 4 rats showed blood-stained ascites with numerous small tumour nodules covering the peritoneum and the under surface of the liver. Microscopically the tumour was a fibro-sarcoma (Fig. 2), consisting of intertwining bundles of spindle-shaped cells, having round or oval nuclei. Mitoses, both normal and abnormal, were frequent and occasional bizarre, multinucleate giant cells were seen. Sections of the liver showed direct invasion of the parenchyma from the capsule.

Oppenheimer *et al.*<sup>6,7</sup> reported the development of tumours in 8 out of 23 animals similarly treated, and stated that the shortest time taken for the production of a tumour measuring 8 mm in diameter was 362 days from the time of kidney wrapping. The carcinogenic action of the

Fig. 1. Kidney with surrounding tumour showing direct invasion at lower pole ( $\times 1.5$ ).

Fig. 2. Fibrosarcoma composed of bundles of spindle-shaped cells (haematoxylin and eosin  $\times 620$ ).

cellulose wrapping has been confirmed in this series, but the time of development of the tumours has been shown to be considerably shorter than in previous reports.

The observations preclude the method for the production of a colony of renal hypertensive rats for long-term observations, but may provide a useful method for the induction of experimental sarcoma in a cancer research programme.

# 1-Methyl-8 $\beta$ -carbobenzyloxy-aminomethyl-10 $\alpha$ -ergoline, a Potent and Long-lasting 5-Hydroxytryptamine Antagonist

It has been proved that derivatives of 8-methylergoline and 8-methylergoline specifically antagonize 5HT. In this group of substances the more active are *d*-lysergic acid diethylamide (LSD<sub>25</sub>) and 1-methyl-*d*-lysergic acid butanolamide (UML<sub>491</sub>). We now report a potent and exceptionally long-lasting 5HT antagonist, namely the 1-methyl-8  $\beta$ -carbobenzyloxy-aminomethyl-10  $\alpha$ -ergoline (MCE), a new compound synthesized in our laboratories<sup>1</sup>, the structural formula of which is:

Its *LD*<sub>50</sub> is 85 mg/kg intraperitoneally and 430 mg/kg *per os* in mice; more than 800 mg/kg *per os* in rats; and about 20 mg/kg intravenously in rabbits. This new compound has been tested for its pharmacological actions both *in vitro* and *in vivo*. The results obtained *in vitro* are summarized in Table 1. All the aqueous solutions were made with the aid of maleic or ascorbic acid in slight excess. When administered *per os* the compound was suspended in 5 per cent gum acacia.

*ED*<sub>50</sub> = Concentration producing 50 per cent inhibition of the spasmodic effects of the agonists, estimated graphically.

In all the experiments antagonists have been applied only 3 min before agonists.

On the isolated guinea-pig ileum UML<sub>491</sub> is often spasmodic at concentrations from 1  $\mu$ g/ml upwards.

To study the anti-5HT action on isolated oestrous rat uterus we followed the procedure described by Stone *et al.*<sup>2</sup> in the work on 1-methyl-4-(5-dibenzo- $\alpha$ ,  $\epsilon$ -cycloheptatrienylidene)-piperidine hydrochloride (cyproheptadine), employing Tyrode's solution at 32° C.

On this test and with this procedure, after a single exposure to the extraordinarily low concentration of 0.00001  $\mu$ g/ml. of MCE the action of 5HT was reduced by about 50 per cent.

MCE behaves like cyproheptadine. In fact little or no inhibition occurs when the antagonist is present along with 5HT in the organ bath. After its removal by washing, the inhibitory activity gradually appears and becomes more and more evident at successive administrations of 5HT. UML<sub>491</sub> inhibition has a relatively rapid onset and reaches its maximal effect more rapidly than MCE. The comparison between the doses which produce about 50 per cent inhibition of the height of contractions shows that MCE is at least 500 times more potent than UML<sub>491</sub>.

At higher concentrations MCE irreversibly blocks the 5HT uterine receptors. MCE exerts a specific anti-5HT action on the uterine receptors. In fact, it reduces to half the spasmodic action of bradykinin and acetylcholine at concentrations at least a million times higher than those active against 5HT. Strangely enough, MCE as UML<sub>491</sub> has no specific anti-5HT activity on guinea-pig ileum. The inhibition of different spasmodic agents like acetylcholine, histamine, bradykinin and edoquin exerted on different smooth muscle preparations by MCE at high concentrations is probably due to a myolytic papaverine-like action of the compound.

*In vitro*, MCE has a weak adrenolytic activity on isolated guinea-pig seminal vesicles.

The results obtained *in vivo* are summarized in Table 2.

Table 2 shows that MCE *in vivo* is a potent 5HT antagonist, without any appreciable antiadrenaline, antihistamine, antiedoquin, antibradykinin and parasympatholytic action.

\* Doepfner, W., and Cerletti, A. (ref. 3).

† Konetzki, H., and Röscher, R. (ref. 4).

*ED*<sub>50</sub> = Dose producing 50 per cent inhibition of the effects of the agonists.

MCE and UML<sub>491</sub> appear to be equipotent when their peak-effects are considered. When their durations of action are compared MCE is far more active than UML<sub>491</sub>. This is clearly shown in Fig. 1.

After subcutaneous administration the *ED*<sub>50</sub> of UML<sub>491</sub> and MCE is similar when their peak-effects (1 h and 3 h after dosing, respectively) are compared. 20 h after administration the *ED*<sub>50</sub> for UML<sub>491</sub> is 75 times higher than at 1 h, whereas that for MCE is only 5 times as high as that at 3 h. Therefore the 5HT antagonism of UML<sub>491</sub> has a rapid onset but it wears off quickly; the inhibitory effect of MCE develops slowly but lasts longer. The comparison of the *ED*<sub>50</sub> 20 h after subcutaneous administration shows that MCE is at least 15 times more potent than UML<sub>491</sub>. The guinea-pig bronchospasm is probably the best test to show the long-lasting effect of MCE. For instance, 15  $\mu$ g/kg of MCE, administered subcutaneously, reduce by 50 per cent the bronchospastic effects of 5HT for 24–48 h. To obtain the same block with UML<sub>491</sub> a dose more than 100 times as high is required.

Some of the 5HT effects *in vivo* are not antagonized even by relatively high doses of MCE: in dogs the effects of 5HT on respiration (hyperpnoea and tachypnoea followed by short-lasting apnoea) and in rabbits the 5HT effects on circulation and respiration (hypotension, bradycardia and apnoea). In this respect MCE behaves like UML<sub>491</sub>.

At a dose of 1 mg/kg, administered intravenously, MCE has no action on the blood pressure and respiration of dogs and cats and does not modify coronary and femoral blood flow and heart contractile force in dogs.

## HAEMATOLOGY

## Availability of Platelet Factor 3 and Activation of Factor XII in Thrombasthenia

RECENT reports by Hardisty, Dormandy and Hutton<sup>1</sup>, Hardisty and Hutton<sup>2</sup>, and Spaet and Cintron<sup>3</sup> have demonstrated that incubation of platelet-rich plasma with kaolin shortens the recalcification<sup>1,2</sup> and Russell's viper venom ('Stypven')<sup>3</sup> times of the mixture. These authors concluded that the effect resulted from availability of platelet coagulant activity (platelet factor 3 availability). Since the activity is confined to the sediment of the centrifuged mixture, is related to the platelet concentration and the anticoagulant used (citrate or ethylenediamine tetraacetic acid), it appears to be related to a surface influence of kaolin, accompanied by adhesion and aggregation of the platelets. In the recalcification system, Hardisty *et al.*<sup>1</sup> detected a marked abnormality with thrombasthenic platelets, which they suggested may be correlated with the failure of these platelets to react with adenosine diphosphate (ADP). We have examined nine thrombasthenic patients by the simultaneous use of the global recalcification test of Hardisty *et al.*<sup>1,2</sup> and the more specific Stypven time according to Spaet *et al.*<sup>3</sup>. In addition the activation of Factor XII was followed and the results indicate the existence of a further *in vitro* defect in thrombasthenia.

The kaolin clotting time was performed under the conditions described by Hardisty *et al.*<sup>1</sup>. The results confirm the findings of these authors in that the abnormality in thrombasthenic platelet-rich plasma was constant in all patients and over a range of platelet concentrations (Fig. 1). As already shown by Hardisty *et al.*<sup>1</sup>, we have confirmed that the abnormality is platelet-specific and not influenced by the presence of activated normal platelet-poor plasma.

Activation experiments were also performed as described by Spaet and Cintron<sup>3</sup> using Stypven. Fig. 2 illustrates the range of the results of clotting times of platelet-rich plasma of 9 control and 8 thrombasthenic subjects. There is clear differentiation into two groups, clotting time always being longer with patient platelet-rich plasma. Activated normal platelet-poor plasma gave results within the patient range.

In an identical system to that described by Spaet and Cintron<sup>3</sup> the activation of Factor XII was tested on a congenitally deficient stored substrate plasma. The results are illustrated in Fig. 3 and represent the range of 14 control experiments and 10 performed with thrombasthenic platelet-rich plasma. Initial activation is identical in platelet-rich plasma and platelet-poor plasma of patients

Fig. 1. Anti-5HT action of UML<sub>491</sub>, administered subcutaneously (●—●) and of MCE administered subcutaneously (○—○) or orally (○---○) at intervals before injection of 5HT to the rat's paw. Ordinate: ED<sub>50</sub> (doses producing 50 per cent inhibition of the oedema) of the antagonists (µg/kg), estimated graphically. Abscissa: time (h) after antagonist administration. The results for UML<sub>491</sub> are in accordance with those obtained by Berde *et al.*<sup>5</sup>

In mice MCE at doses higher than 2 mg/kg, administered intraperitoneally, increases barbiturate toxicity, decreases rectal temperature and reduces spontaneous motility. In rabbits MCE does not antagonize 5-hydroxytryptophan (5HTP) hyperthermia<sup>6</sup> at the dose of 1 mg/kg, administered subcutaneously.

According to Tedeschi *et al.*<sup>7</sup>, anti-5HT drugs, with an anti-5HT action on the central nervous system, antagonize the convulsant effects of tryptamine in rats. On this test we found that MCE behaves like 2-brom-*d*-lysergic acid diethylamide (BOL<sub>148</sub>), LSD<sub>25</sub>, and like chlorpromazine as described by these authors.

Its subcutaneous ED<sub>50</sub>, 3 h after administration, is about 75 µg/kg. Summing up, the new synthetic compound 1-methyl-8 β-carbobenzoyloxy-aminomethyl-10 α-ergoline (MCE) is a very active and specific antagonist of 5HT. Its acute and subacute toxicities are low<sup>8</sup> and its absorption from the gastro-intestinal tract is good (Fig. 1).

Owing to these favourable properties and to its extraordinarily long-lasting action MCE appears to be a suitable agent to study the still unknown part played by 5HT in human physiology and pathology.

We thank Sandoz Ltd. (Switzerland) for generous supplies of UML<sub>491</sub> and bradykinin, and Dr. C. D. Bianchi for his help in translating the test.

<sup>8</sup> Bertauxoll, O. (personal communication).

Fig. 1. The recalcification time of normal (●) and thrombasthenic (×) platelet-rich plasma after incubation with kaolin. The mixture containing 0.1 ml. platelet-poor plasma, 0.1 ml. platelet-rich plasma at the concentrations shown and 0.1 ml. kaolin (20 mg/ml. in buffered saline) was incubated at 37° C for 20 min and recalcified with 0.2 ml. calcium chloride 0.025 M. Each point represents the mean of 1-7 tests each performed in duplicate. The range of the mean of multiple tests is illustrated.

Fig. 2. Platelet Factor 3 availability measured by the Stypven time in controls and thrombasthenia. Incubation mixture was 0.5 ml. platelet-rich plasma and 0.1 ml. kaolin 50 mg/ml. at 37° C. 0.1 ml. of the mixture was transferred to a tube containing 0.1 ml. calcium chloride 0.025 M and 0.1 ml. Stypven 1:100,000 and the clotting time recorded.

Fig. 3. Factor XII activation in platelet-rich plasma of controls and thrombasthenic patients. Activation mixture as before (Fig. 2). Sub-samples were diluted 1:20 in V.B.S. and 0.1 ml. of the diluted mixture transferred to a tube containing 0.1 ml. substrate plasma, 0.1 ml. 'Cephalin' (ref. 6) and 0.1 ml. kaolin (20 mg/ml. in V.B.S.) and recalcified. All additions to the substrate were made within 30 sec of testing.

and controls. However, activation continues in the control platelet-rich plasma and is maximal at 15 min, whereas normal platelet-poor plasma and the patients' platelet-rich plasma show no, or minimal, further activation.

These results indicate a parallel abnormality with thrombasthenic platelets measurable by recalcification, by the Stypven time and by a defect in the activation of Factor XII. It was therefore believed possible that platelet Factor 3 availability may depend on coincident optimal Factor XII activation or that Factor XII activation may influence the results of both tests. However, as already shown by Hardisty and Hutton<sup>3</sup>, congenitally deficient Factor XII platelet-rich plasma was found to give normal coagulation times in the presence of activated normal platelet-poor plasma, in the recalcification system. Furthermore, the Stypven times of kaolin activated Factor XII deficient platelet-rich plasma were normal even in the absence of normal plasma (Fig. 4). The latter test is therefore independent of Factor XII activation and seems to measure platelet activity more specifically. This is also confirmed by our observation that the addition of a partially purified contact product, prepared according to Wessler<sup>4</sup>, to a normal platelet-rich plasma or platelet-poor plasma does not influence the Stypven time.

If platelet aggregation is essential for the availability of platelet Factor 3, as is suggested by the defect in thrombasthenia, then it would be expected that the addition of a sufficient concentration of ADP would shorten the Stypven time of normal platelet-rich plasma in the

Spaet<sup>5</sup> assay. This was confirmed by the findings illustrated in Fig. 5, which demonstrates sub-optimal availability of platelet Factor 3, as the activity is less than that observed with kaolin. These results support the findings of Mustard, Hegardt, Rowsell and MacMillan<sup>1</sup> working with native platelet-rich plasma, who demonstrated, with the prothrombin consumption test, increased coagulant activity after ADP-induced aggregation. On the other hand, Hardisty and Hutton<sup>3</sup> were not able to demonstrate this effect of ADP, but the discrepancy is explicable on the basis of the ADP concentration utilized by these authors.

These results confirm the existence of a defect in the availability of platelet Factor 3 in thrombasthenia and indicate the presence of an unrelated abnormality of surface activation. It is probable that both defects result from the inaggregability of these platelets. The significance of the tests described by Hardisty *et al.*<sup>1,3</sup> and Spaet and Cintron<sup>5</sup>, in terms of platelet function, is the same, provided that plasma abnormalities are corrected in the first. The Stypven assay is more specific in the measure of platelet Factor 3 availability, in the sense that it is independent of the contact phase of plasma activity and the Factor XII activation induced by kaolin. The exact roles of platelet adhesion<sup>1,3</sup>, or of aggregation<sup>5</sup>, and of an eventual abnormality of the platelet membrane in thrombasthenia, remain to be established. It must also be considered that there may be little correlation between these *in vitro* abnormalities in thrombasthenia, hitherto unrecognized, and a real coagulation defect in this disease.

Fig. 4. The Stypven times and Factor XII activation in a control subject and one case of Hageman deficiency. The results of the control are represented by solid lines and those of the patient by broken lines.

Fig. 5. Platelet Factor 3 availability measured by the Stypven time after ADP induced aggregation in relation with the final concentration of ADP, in normal platelet-rich plasma and platelet-poor plasma. Results with kaolin are illustrated below for comparison.

*Note added in proof.* Since this communication was submitted, Horowitz<sup>7</sup> has reported similar findings with 'Celite' incubated platelet-rich plasma and the Stypven time.

### Haemoglobins of Adult and Foetal African Elephants

THE numerous special properties of human foetal haemoglobin (HbF) as compared with those of the human adult (HbA) have been rather thoroughly investigated<sup>1,2</sup>. Fewer data, however, are available on other mammalian foetal haemoglobins<sup>3,4</sup>.

In comparison with the adult blood pigment the characteristic alkali stability, slow electrophoretic mobility, and tryptophan band of human HbF were missing in the animal foetal haemoglobins previously examined, with the exception of the rhesus monkey<sup>5-7</sup> and the chimpanzee<sup>8</sup>. The isoleucine content is greater in all foetal haemoglobins compared with adult haemoglobin<sup>9</sup>, so far as is known.

This communication presents results on electrophoresis, alkali denaturation, ultra-violet spectrum, and potassium ferricyanide oxidation of adult and foetal haemoglobin from the African elephant (*Loxodonta africana*).

Pregnant elephants were shot during game control measures in the Masindi and Fort Portal areas of Uganda. It was possible to remove the specimens of blood within 0.5 h of the animals' death, and transport them in Dewar flasks to a mobile laboratory for investigations. Blood

specimens were examined from five adult elephants and two foetuses with ages of 5 months (foetus 1) and 12 months (foetus 2), respectively<sup>10</sup>.

In starch-block electrophoresis (veronal-veronal-sodium buffer, pH 8.8) and in starch-gel electrophoresis (tris-EDTA-borate, buffer, pH 9.0), only foetus 1 yielded two haemoglobin fractions. The haemoglobin from foetus 2 was identical with that of adult elephants. The slowly migrating fraction of foetus 1 (Fig. 1) represented 15 per cent of the entire pigment. The relative electrophoretic migrating velocities of adult human and African elephant haemoglobins agree substantially with those found by other investigators<sup>11,12</sup>.

No qualitative or quantitative differences in the kinetics of alkali denaturation<sup>13</sup> between the foetal haemoglobin and the adult haemoglobins were observed. The amount of alkali-resistant blood pigment from all investigated elephants was found to range between 95 and 97 per cent.

A 15 per cent labile fraction in the entire cyanmethaemoglobin haemolysate from foetus 1 was found during heat denaturation. This fraction corresponds quantitatively to the slowly migrating electrophoretic component. The haemoglobin from foetus 2 gave results identical with those of the adult elephants. Human HbF, in comparison with HbA, is less resistant<sup>14</sup>. The ultra-violet spectro-analysis (Fig. 2) of the slowly migrating fraction of foetus 1 showed, in contrast to the fast-migrating fraction and the adult haemoglobins, the typical tryptophan band which is known to be characteristic for human HbF<sup>15</sup>.

Fig. 2. Absorption spectra in the ultra-violet of the slow- and fast-moving haemoglobin of foetus 1 compared with the blood pigment of adult elephants

Fig. 1. Separation of haemoglobins by starch-gel electrophoresis at pH 9.0. From left to right, adult elephant, foetus 1, foetus 2, human cord blood, human adult blood. Horizontal line, that of application

The potassium ferricyanide oxidation proceeded three times faster in the slowly migrating fraction than in the fast-migrating fraction of foetus 1 and the adult elephant haemoglobin. As previously shown, the same differences exist in the oxidation speed between foetal and adult human blood pigment. It was concluded that the potassium ferricyanide oxidation is related to the dissociation of oxygen from haemoglobin<sup>16</sup>.

It can be stated, therefore, that a foetal haemoglobin was found only in the 5-month-old foetus and not in the 12-month-old foetus of the African elephant, the gestation time of which is 21 months. With the exception of alkali

denaturation, elephant foetal haemoglobin showed physico-chemical similarities to human HbF.

From a biological point of view it is interesting that blood from the older foetus has a higher oxygen affinity under standard conditions of temperature and pH than the blood of the younger<sup>17</sup>.

## HISTOCHEMISTRY

### Use of Galactose Oxidase in the Histochemical Examination of Mucus- secreting Cells

GALACTOSE oxidase is an enzyme which oxidizes the primary alcohol group of galactose or galactosamine to an aldehyde<sup>1</sup>. The enzyme attacks not only free galactose but also terminal non-reducing galactose and galactosamine units when glycosidically linked. Detection of such units in mucopolysaccharides and mucoproteins produced by mucus-secreting cells can be accomplished by staining the aldehyde produced with Schiff's reagent.

Material collected from the slaughterhouse was fixed in 10 per cent formol-saline, and specimens were wax-embedded and cut at 4 $\mu$ . The sections were first treated with a solution of 0.4 per cent sodium borohydride containing 0.4 per cent sodium bicarbonate at room temperature for 1 h in order to reduce Schiff-staining groups already present in the tissues. After a wash in running water for 5 min the sections were treated with a solution containing 2-3 units per ml. of galactose oxidase (prepared according to Amaral *et al.*<sup>2</sup> but now obtainable from Worthington Biochemical Corporation, Freehold, New Jersey) and 1 per cent by volume of catalase (Boehringer and Soehne G.m.b.H., Mannheim, Germany) in 0.03 M-tris hydrochloride buffer, pH 7, at room temperature for 2 h. Following another wash in running water for 5 min, the sections were stained with Schiff's reagent<sup>3</sup> for 3 min, then rinsed in sulphurous acid for 4 min and in running water for 10 min. Aldehyde groups produced by the action of galactose oxidase were stained red by this reagent,

but the intensity of staining was less than that produced by periodic acid-Schiff staining because less aldehyde groups were produced by this method.

Sections of bovine cervix taken from a cow at pro-oestrus showed a great variation in intensity of staining from cell to cell, as is shown in Fig. 1. Some cells were not stained at all, whereas others were stained relatively strongly. This indicated that the mucus in the cells of the cervical epithelium was heterogeneous with regard to the number of terminal non-reducing galactose and galactosamine groups present. Another possibility is that the linkage of galactose and galactosamine to the penultimate sugar varied from cell to cell since that has been shown to cause variation in the rate of oxidation of model disaccharides by galactose oxidase (Roberts, G. P., unpublished results). However, since a treatment for 2 h with galactose oxidase is sufficient to oxidize all the available galactose and galactosamine groups, this later theory is considered unlikely.

Ovine submaxillary gland sections were not stained by this procedure, as is to be expected from the structure of the mucoprotein isolated from this source, most of the galactosamine units being substituted at the primary alcohol group by a sialic acid residue<sup>4</sup>. However, when the sections were subjected to an overnight incubation with neuraminidase, subsequent treatment with galactose oxidase produced aldehyde groups which could be stained with Schiff's reagent.

In order to obtain information about the linkage of sialic acid in sections of bovine cervix, all the terminal non-reducing galactose and galactosamine units already present were first oxidized with galactose oxidase for 2 h as already described. The aldehyde groups thus produced were then blocked by the aniline chloride method of Lillie<sup>5</sup> using a 2-h reaction time. Completeness of oxidation and blocking was checked at this stage by re-oxidizing with galactose oxidase and staining with Schiff's reagent. No staining was produced, thus confirming the effectiveness of this treatment. Sialic acid was then removed from the aniline chloride blocked sections by an overnight incubation at 37° C with a solution containing 0.004 per cent by weight of neuraminidase (Sigma Chemical Co., St. Louis, Missouri) and 10<sup>-4</sup> M calcium chloride in 0.1 M sodium acetate buffer, pH 5.1. Treatment of these sections with galactose oxidase produced aldehyde groups in some cells as shown by Schiff staining (Fig. 2). Here again there was a great variation in intensity of staining from cell to cell. This result indicated that at least some of the sialic acid in the mucus-secreting cells of the bovine cervix is linked to galactose and galactosamine. It is not possible at this stage to identify by histochemical means

Fig. 1. Bovine cervix treated sequentially with 0.4 per cent sodium borohydride containing 0.4 per cent sodium bicarbonate/galactose oxidase/Schiff's reagent.

Fig. 2. Bovine cervix treated sequentially with galactose oxidase/aniline chloride/neuraminidase/galactose oxidase/Schiff's reagent.

which of these two sugars is involved. This result suggests a heterogeneity in the mucus of bovine cervical epithelium with regard to sialic acid linkage.

We thank Dr. E. I. Garvie for advice and assistance in culturing *Dactylium dendroides* from which the galactose oxidase was prepared, Mr. N. G. J. Gruber for photographing the sections, and Dr. R. A. Gibbons for his advice.

## HISTOLOGY

### Lesion of the Bone Matrix in Vitamin D-resistant Rickets

MICROBADIOGRAPHIC examination of compact bone from patients with vitamin D-resistant rickets has revealed that, in addition to the presence of wide osteoid borders, there is a lack of mineral around osteocyte lacunae and their canaliculi<sup>1,2</sup>. Histological examination of decalcified material hitherto has failed to demonstrate any abnormality in the organic matrix at these sites, suggesting the presence of mineral deficiency only<sup>3</sup>. We have obtained evidence for a lesion of the bone matrix, however, by applying the following modification of Schmorl's method<sup>4</sup>.

Compact bone from the fibulae of 2 patients (a 22-year-old male and a 17-year-old female) was removed in the course of orthopaedic procedures. It was fixed for 24 h in a mixture of formalin, mercuric chloride and picric acid in water, and afterwards for 2 days in 10 per cent formalin. Decalcification was carried out in 18 per cent ethylenediamine tetraacetic acid in water at pH 7.1 and 40° C for 3 days. Following this, the material was rinsed in water and cut in the frozen state at 20 μ. The sections were

stained in 0.01 per cent azure II in water (pH adjusted to 9.0 with ammonium hydroxide) for 30 min, rinsed and transferred to a solution of 20 ml. saturated picric acid in 200 ml. water. After a final rinse, the sections were mounted in laevulose.

In normal bone azure II heavily stains the walls of the lacunae and canaliculi. In bone from these patients, the stain was also concentrated at the sites where the mineral was lacking (Figs. 1 and 2). The localization of this abnormal pattern was not strictly perilacunar but rather extending from the lacunae toward the centre of the osteone, along the centripetal canaliculi. This pattern has been observed before in undecalcified bone sections on treatment with basic fuchsin<sup>4</sup>. The normal lamellar architecture of the matrix appeared to be interrupted at these sites. At high magnifications it was noted that neither lacunae nor canaliculi were enlarged and that the matrix around the canaliculi had taken up the stain in a distinct globular pattern. These globules measured up to 1 μ in diameter. Non-mineralized osteoid, for example at the inner circumference of growing osteones, did not take up the stain.

Attempts to determine the nature of the matrix-compound, which was responsible for the affinity for azure II, have so far yielded negative results. Prior digestion of the sections with pepsin and trypsin did not interfere with the pattern as revealed by azure II. Haematoxylin-, periodic acid-Schiff-, van Gieson-, Mallory- and sudan black-stains, as well as the acrolein-Schiff reaction for protein<sup>5</sup>, failed to bring out the lesion. Alcian blue was localized at these sites only very occasionally and in low concentration.

Fig. 1. Microradiograph of 100 μm undecalcified section from a 17-year-old patient with vitamin D-resistant rickets (× c. 200).

Fig. 2. 20 μm decalcified section from same patient, stained with azure II-picric acid (× c. 200).

The density of the perilacunar and pericanalicular regions to very soft (3 kV) X-rays was indistinguishable from the normal. In phase-contrast microscopy of 20 $\mu$  decalcified sections, the lesion was visible as a conglomeration of small dots, interrupting the lamellar pattern of the osteons.

These findings are consistent with the possibility that a physical characteristic rather than a chemically defined moiety of the matrix is responsible for the observed affinity for azure II. The lack of mineral around lacunae and canaliculi may be the result of impaired mineralization or of demineralization *in vivo*<sup>4</sup>. It is conceivable that a structural change in the matrix is involved in either of these processes and is revealed by the described deposition of azure II.

It is unlikely that the lesions resulted from long-continued treatment with high doses of vitamin D, as one of the patients had not received any vitamin D for 4 years.

Lipid in the Matrix of Ageing Articular Cartilage

It is well known that with ageing, lipid material appears in the matrix of hyaline cartilage in the immediate vicinity of the cells, in the form of 'haloes' around the lacunae<sup>1</sup>. In the course of a histochemical and quantitative investigation of the lipid content of human cartilage, it has been observed that a more diffuse impregnation with fat occurs with ageing in the superficial zone of articular hyaline cartilage.

Post-mortem and amputation material has been used from 85 subjects ranging from 2 days to 80 years of age. Specimens from macroscopically normal areas have been taken from the medial femoral condyle of the knee joint (other joints being used as the source in two cases), fixed in formal calcium, and 10 $\mu$  frozen sections coloured with sudan black B in propylene glycol. Where a positive result has been obtained, the tissue had been subjected further to the Nile blue<sup>2</sup> and acid haematein techniques<sup>3</sup>, pyridine extraction being used as a control. In addition to the normal areas, a few osteoarthritic patches have been studied.

In cartilage from subjects under the age of 20 years, lipid cannot be detected in the matrix of the superficial zone. From the third decade onwards, however, a sudan-

Fig. 1. Articular cartilage from medial femoral condyle of subject aged 80 years (sudan black  $\times 75$ )

Fig. 2. Osteoarthritic cartilage from area adjacent to normal tissue shown in Fig. 1 (sudan black  $\times 75$ )

ophilic layer in this zone can be seen in an increasing proportion of the individuals studied (see Table 1 and Fig. 1). This layer varies both in depth and in staining intensity as seen in transverse section, both features tending to increase with age. The sudanophilic material is extractable with pyridine and the corresponding area is stained red and black by the Nile blue and acid haematein techniques respectively, thus denoting the presence of both neutral fat and phospholipid. In the osteoarthritic areas studied, no lipid layer could be seen (Fig. 2). No correlation was established between the presence of the lipid and the state of nutrition of the subject, although this may be due to the small number investigated.

The problem arises as to the origin of this lipid material. Fat is a normal and constant constituent of the chondrocyte<sup>4</sup> and presumably some extracellular fat may derive from the cell it surrounds, although the appearance of fat in the matrix thus can scarcely be considered physiological<sup>1</sup>. In an ultrastructural study of articular cartilage, Barnett *et al.*<sup>5</sup> describe the degeneration of superficial cells *in situ*, leaving a residuum of myelin figures and osmiophilic granules in the matrix. This mechanism could also contribute to the appearance described here.

Table 1

Age group	No. cases	Diffuse lipid layer in superficial zone	
		Present	Absent
0-20 years	6	0	6
21-40 years	7	4	3
41-60 years	11	10	1
61-80 years	10	8	2
81-	1	1	0

However, the uniform nature of the lipid distribution suggests that a diffusion process from the synovial fluid may take place; on this point it may be relevant that cartilage is readily permeable to lipid-soluble materials\*. Such diffusion could be a post-mortem phenomenon although, were this so, it seems probable that it would be manifest in young as well as old subjects, and in osteo-arthritis as well as normal areas.

The existence of this lipid-rich zone in life could influence or modify the nutrition of the cartilage cells, at least in so far as the free circulation of aqueous fluid through the matrix is concerned. Such an effect has been demonstrated in a 'Millipore' filter by Rendi and Reid<sup>7</sup>. However, until the work reported here has been extended, no interpretation as to significance can be made.

I thank Prof. R. C. Curran and his staff for access to post-mortem material.

## IMMUNOLOGY

### Passive Transfer of 'Allergic' Encephalomyelitis with Antibrain Serum Injected into the Lateral Ventricle of the Brain

It is generally believed that experimental allergic encephalomyelitis results from an interaction between nervous tissue antigens and cells which are engaged in a delayed hypersensitive response. Although experimental allergic encephalomyelitis can be followed by circulating antibodies that react *in vitro* with nervous tissue constituents, all experiments designed to transfer passively experimental allergic encephalomyelitis either with sera from diseased animals or with antibrain immune sera have failed<sup>1</sup>. This has been taken as evidence that antibody does not play any significant part in the development of experimental demyelinating disease<sup>2</sup>. A possible explanation for the failure of antibrain antibodies to induce encephalomyelitic lesions may be their inability to cross the blood-brain barrier in sufficient amount. In order to test the role of antibrain antibodies in the pathogenesis of experimental allergic encephalomyelitis, guinea-pigs with a cannula inserted permanently into the lateral ventricle of the brain were used in the present experiment. Administration of serum through the cannula by-passes the blood-brain barrier, and permits direct contact of injected antibodies and nervous tissue.

Experimental allergic encephalomyelitis was induced in guinea-pigs by a single intradermal injection over the sternum of 0.1 ml. of the following mixture: 0.5 g of fresh bovine spinal cord, or 200 mg of cord lipid, and 3 ml. of paraffin oil containing 9 mg of *Mycobacterium tuberculosis*. Sera from animals showing histological signs of disease were heated at 56° C, pooled, passed through a Seitz filter and stored at -20° C for three months. A complement-fixation assay revealed antibody to spinal cord lipid at a titre of 1/50.

A permanent cannula<sup>3</sup> designed especially for guinea-pigs was implanted into the left lateral ventricle. Operated animals were injected with sterile saline for three successive days, and thereafter with pooled sera from experimental allergic encephalomyelitis animals. Each animal received two 0.1 ml. injections of serum daily with a 12-h interval

between injections. Control cannulated guinea-pigs were treated with normal guinea-pig serum. Animals were observed carefully during the treatment, and those with weakness were killed. Paraffin sections of cerebrum, cerebellum and three levels of spinal cord were processed for haematoxylin-eosin staining. Some representative sections were stained for myelin using the Weigert-Pal technique. The intensity of disease was judged according to the extent of histological lesions.

Table 1 summarizes the incidence of experimental allergic encephalomyelitis in guinea-pigs injected intraventricularly with homologous antibrain or normal serum. Seven of eleven animals treated with serum from diseased guinea-pigs showed mild but definite lesions on histological examination. Two guinea-pigs of this group developed inflammatory lesions within three days of the beginning of treatment, that is following administration of only 0.6 ml. of antibrain serum. Histopathological changes in the nervous system were of minimal intensity, but characteristic of delayed hypersensitive reactions with demyelination. The lesions consisted of histiocytes and lymphocytes; no polymorphonuclear cells were noted. Most of the lesions were localized in the vicinity of the lateral ventricles, and some aggregates of mononuclear cells were situated directly beneath the ependyma. Small perivascular collections of inflammatory cells were observed in cerebrum, occasionally in cerebellum and spinal cord. Sections of control animals injected with normal serum were completely negative.

Table 1. EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (HAE) FOLLOWING PASSIVE TRANSFER OF ANTIBRAIN SERUM INTO THE LATERAL VENTRICLE OF THE BRAIN

Group	No. of guinea-pigs with HAE lesions	
	Negative	Positive
Treated with antibrain serum	4	7
Treated with normal serum	10	0

The present experiment demonstrates that experimental allergic encephalomyelitis can be passively transferred by administration of experimental allergic encephalomyelitis serum directly into the lateral ventricle of the brain. Although the antibody system involved in the demyelinating process is not characterized, it seems that antibrain antibody can elicit an immune response *in vivo* relevant to the pathogenesis of 'allergic' encephalomyelitis. The observations presented here offer *in vivo* evidence to support the *in vitro* findings of Bornstein and Appel<sup>4</sup> showing that a fraction of rabbit experimental allergic encephalomyelitis serum demyelinated myelinated cultures of rat or mouse cerebellum. Using the fluorescent antibody technique Sherwin *et al.*<sup>5</sup> demonstrated that antibodies with a specificity for myelin are present in the sera of rabbits immunized with spinal cord. The suppressive effect of complement-fixing antibrain antibody, described by Paterson and Harwin<sup>6</sup>, is not inconsistent with this report. It may be due to an antibody which has 'enhancing' properties such as certain factors demonstrable in tissue transplantation immunity. It should be mentioned that meningo-vascular lesions have been produced by means of intracisternal injection of heterologous antibrain sera<sup>7</sup>, but the character of the lesions was different from the injury seen in experimental allergic encephalomyelitis and in this investigation.

The mechanism which underlies the induction of experimental allergic encephalomyelitis by antibrain antibody is not clear, and several possibilities should be taken into account<sup>8,9</sup>. It appears that the pathogenesis of experimental allergic encephalomyelitis is more complex than was originally believed, and that in addition to sensitized cells of 'delayed' type and cell-bound antibody, circulating antibody can also take an active part in the mechanism responsible for demyelinating disease. Although this is possible, it could be argued that antibrain antibodies can attack brain *in vivo*, thus causing the lesions which are reminiscent of those of experimental allergic encephalomyelitis.

### Effect of Trypsin Inhibitor Isolated from Sows' Colostrum on the Absorption of $\gamma$ -Globulin by Piglets

It is generally held that the absorption of whole proteins by piglets occurs only during the first two days of life. By this mechanism the baby pig acquires antibodies. For the first 5 days *post partum* the sow's colostrum contains a trypsin inhibitor<sup>1</sup> and it has been suggested<sup>2</sup> that the action of the trypsin inhibitor is to prevent the digestion of  $\gamma$ -globulins, so allowing the piglet to absorb them intact. Extending this theory further, it can be postulated that whole protein absorption ceases when there is insufficient inhibitor in the colostrum to inactivate all the trypsin entering the gut.

We prepared a solution of trypsin inhibitor from sow's colostrum according to the method of Leaskowski *et al.*<sup>3</sup>. The potency of the solution expressed in the units of Kunitz<sup>4</sup> was  $200 \times 10^4$ /ml. Each ml. of solution was capable of inactivating 30 mg of the sample of crystalline trypsin used in the assay. Sow's colostrum was chosen as starting material as it was thought that the inhibitor it contained could well be more effective *in vivo* than either the soya bean or bovine colostrum proteins used by earlier workers<sup>5,6</sup>. Leaskowski *et al.*<sup>3</sup> have demonstrated important differences in the properties of inhibitors isolated from these sources that show them to be different substances, so it seemed advisable to use the native protein.

Samples of  $\gamma$ -globulin were prepared by a combination of sodium sulphate precipitation and fractionation on a DEAE cellulose column from pig serum. The  $\gamma$ -globulin was labelled with iodine-131 by the method of McFarlane<sup>7</sup>.

Quantitative portions of labelled  $\gamma$ -globulin were given to two piglets in a litter of eight, 2 h after birth. Blood samples were taken 12 h later and the serum volumes of the piglets were estimated. Calculation showed that about 13 per cent of the activity administered was present in the serum protein.

The remaining six piglets were given a single dose of labelled  $\gamma$ -globulin at 60 h of age. Blood samples were taken 12 h later and serum volumes were calculated. With one exception, only negligible amounts (0.3–0.9 per cent) of activity were present in the serum proteins. One piglet still absorbed much  $\gamma$ -globulin (11 per cent in serum protein). This animal was discarded. The five remaining piglets were divided into an experimental group of three animals, each of which received 4 ml. trypsin inhibitor each hour from 74 h onwards, and a control group of two animals, given 4 ml. of distilled water each hour. At 80 h, all five animals received a second dose of labelled  $\gamma$ -globulin, accompanied by trypsin inhibitor or water. Doing with trypsin inhibitor or water continued for a further 12 h (92 h of age), when blood samples were taken and serum volumes estimated. During the 18-h period

(74–92 h of age) each piglet in the experimental group received inhibitor equivalent to at least 1 l. of colostrum<sup>1</sup>. There was no increase in either group in the quantity of labelled  $\gamma$ -globulin detectable in the precipitated serum protein fraction.

This result indicated that this inhibitor is incapable of inducing the absorption of  $\gamma$ -globulin in 3-day-old piglets. It would seem that the disappearance of trypsin inhibitor from colostrum does not account for the cessation of absorption of  $\gamma$ -globulin.

We thank Dr. W. A. Hemmings for preparing the labelled  $\gamma$ -globulin and the Pig Industry Development Authority for financial assistance.

### Spontaneous Occurrence of Autoantibodies Cytotoxic to Thymus Cells in the Sera of Mice of the 129 Strain

AUTOANTIBODIES of various types appear in the serum during autoimmune diseases; but it is not clear whether they are the cause or the result of the pathological process. Grabar<sup>1</sup> and Boyden<sup>2</sup> have postulated that autoantibodies are constantly present in low concentrations in the normal organism, their function being to transport normal catabolic products. This possibility that autoantibodies may have a physiological function was strengthened by the recent detection of autoantibodies in normal human sera<sup>3,4</sup> and in sera of healthy mice<sup>5</sup>. In the work recorded here, sera of normal adult mice of the 129 inbred strain were found to be cytotoxic for thymus cells of mice of strain 129 and of other strains in the presence of guinea-pig serum. Although the nature of the factor in 129 strain mouse serum has not yet been fully established, its behaviour in the cytotoxic test is similar to that of well-defined isoantibodies<sup>6,7</sup>. It will therefore be referred to here as an antibody.

Mice of an inbred 129/Rr colony maintained at New York University Medical School by Dr. E. A. Boyce were used as donors of sera in most experiments. In some experiments the tests were performed with the sera of 129 mice reared in other laboratories (129/J from the Jackson Memorial Laboratory, Bar Harbor, Maine, and 129/Rr from the Immunogenetics Research Unit, Duke University Medical Center, Durham, North Carolina, from which the New York University colony originated). The mice were bled either from the tail or from the retro-orbital sinus. The sera were separated within 5 h after bleeding and were stored at  $-10^{\circ}\text{C}$ . The cytotoxic test was a modification<sup>8</sup> of the method of Gorer and O'Gorman<sup>9</sup>. The guinea-pig serum used as a source of complement was absorbed with washed packed leukaemic cells until all cytotoxic activity against mouse thymus cells<sup>10,11</sup> had been removed. Cytotoxic titres were defined as the highest dilution of serum at which 50 per cent of the cells were killed.

The sera of all 129 mice 5 weeks of age or older contained an antibody which in the presence of guinea-pig com-

plement was cytotoxic for mouse thymus cells. Although the antibody was present in the serum of pregnant mice it was absent in suckling progeny, but appeared during the third week of life. Only thymus cells were sensitive to the cytotoxic effect of normal 129 serum; cells from spleen, bone-marrow, lymph nodes and peritoneal cavity were not affected. The thymus cells of all the strains of mice tested were susceptible, although there were differences in the sensitivities of different strains. Cytotoxic titres of 1:8 to 1:16 were obtained with thymus cells of the *C57BL/6*, *A*, *BALB/c*, and *C57L* strains. Lower titres were obtained with thymus cells of *C3H*, *C58* and *SJL/J* strains. The highest cytotoxic titres (1:16–1:32) were obtained with thymus cells of the 129 strain. Sera of individual 129 mice had the same cytotoxic effect *in vitro* on their own thymus cells as sera of other 129 mice. In no case were 129 thymus cells killed by guinea-pig serum alone, indicating that the cells were not coated with antibody *in vivo*. In the presence of guinea-pig serum, the sera of 129 mice were cytotoxic also for rat thymus cells, but not for rat spleen cells. In addition to its cytotoxic effect on thymus cells the serum of 129 mice was found to have a cytotoxic effect *in vitro* on the transplanted leukaemias *ERLD*, *H<sub>2</sub>RL9* (ref. 12) and a *BALB/c* radiation-induced leukaemia. There was no effect on many other tumour lines (including the sarcomas *Sal*, *BP8*, and the leukaemias *H<sub>2</sub>RL3*, *H<sub>2</sub>RL9*, *HL4* and *K36* (ref. 12)).

While cytotoxic tests thus indicated a specific cytotoxic effect of the 129 normal serum on thymus cells and some leukaemic cells, absorption experiments indicated that the antigen was of more widespread distribution. The cytotoxic activity of 129 serum was absorbed by all nucleated tissues tested, including thymus, spleen, and kidney of the mouse and rat. Cytotoxic activity was removed also by absorption with guinea-pig red cells but not with mouse, sheep and hamster red cells. The antigen from mouse thymus or spleen resisted boiling for 30 min. This treatment did not diminish the capacity of these tissues to absorb the antibody.

The cytotoxic antibody in the serum of 129 mice was destroyed completely by heating at 56° C for 20 min, and was inactivated by treatment with 0.01 M mercaptoethanol for 1 h. Preliminary fractionation by filtration through a 'Sephadex G-200' column, followed by analytical ultracentrifugation, indicated that the antibody is probably a 19S  $\gamma$ -globulin.

The antibody present in the sera of normal 129 mice differs from the autoantibodies previously described in mice<sup>12,14</sup> in its specificity and characteristics: it is cytotoxic in the presence of guinea-pig complement for thymus cells and for some leukaemic cell lines, but is absorbed by many different tissues; it appears earlier in the life of the animal than autoantibodies previously reported, is heat-labile and is probably a 19S  $\gamma$ -globulin.

Sera of individual 129 mice reacted *in vitro* with their own thymus cells. There was, however, no evidence for reaction of the cytotoxic factor with thymus cells *in vivo*, since the thymus cells of 129 mice were not killed by guinea-pig complement alone. The lack of access of the antibody to the thymus cells might be attributed to the separation of the thymocytes from the blood stream by a barrier to macromolecular materials<sup>15,16</sup>. Similarly, the placental barrier, which is relatively impermeable to  $\gamma$ -IM globulins<sup>17</sup>, probably accounts for the absence of the antibody from sera of neonatal mice. No pathological changes, such as are found in *NZB/BL* mice<sup>18</sup>, were found in the thymus of 129 mice. Indeed, the thymus of 129 has served in electron microscopic studies as a prototype of the structure of the normal mouse thymus<sup>19</sup>.

I thank Dr. L. J. Old and Dr. E. A. Boyce for their advice; Dr. H. A. Campbell for help with the column fractionation; Dr. M. Barclay for performing the analytical ultracentrifugations; and Dr. D. B. Amos for the gift of mice.

## RADIOBIOLOGY

### Cysteamine-Induced Increase of Cellular Glutathione-level: A New Hypothesis of the Radioprotective Mechanism

It was reported recently<sup>1</sup> that incubation of *ELD* ascites cells or its sublines in a tissue culture medium supplemented with cysteamine causes an increase of the cellular content of the acid-soluble, non-protein-bound sulphhydryl groups (NPSH). The increase was found to be directly related to the cysteamine concentration in the medium. Expressed in SIF\*, the extent of NPSH increase was similar to the extent of the increased radioresistance expressed in DRF† of human kidney cells or mouse fibroblasts treated with cysteamine at comparable concentrations<sup>2</sup>. This similarity of SIF and DRF has been interpreted<sup>1</sup> as indicating that the mechanism of radioprotection by cysteamine is, in some way, dependent on the increased concentration of NPSH in the protected cell. The nature of this NPSH is not known at present.

Aliquots of freshly withdrawn *ELD* ascites tumour<sup>3</sup>, with a concentration between 150 and 250 × 10<sup>6</sup> cells/ml., were diluted with equal parts of Eagle's tissue culture medium supplemented with various amounts of cysteamine. To controls, the medium was added without cysteamine. 5 ml. volumes of the cell suspensions in closed, 10-ml. glass vials were incubated in a water bath at 37° C, and kept under gentle agitation for a period of 30 min. The cells were then centrifuged at 600g for 10 min and re-suspended in 20 volumes of tissue culture medium without cysteamine. The total NPSH content of the washed cells and the incubation medium were subsequently estimated in duplicate. Ellman's<sup>4</sup> method was used as previously described<sup>5</sup> except that NPSH extraction was made with 6 per cent perchloric acid instead of trichloroacetic acid in order to facilitate the subsequent determination of glutathione (GSH) (ref. 6). Cell counting was performed by a Coulter model B electronic particle counter. The standard error of a single determination of NPSH was 5.7 per cent of the mean as calculated from the differences between duplicate measurements. Of the total NPSH,

\* SIF, Sulphydryl increase factor denotes increase of NPSH relative to untreated controls.

† DRF, Dose reduction factor denotes the increase of radiation resistance relative to untreated controls.

Fig. 1. Non-protein sulphhydryl (NPSH, ○) and glutathione (GSH, ●) level of *E. coli* cells treated with different concentrations of cysteamine, in relation to the level of the respective, untreated controls. The lines represent statistical regression lines with equation  $y = 0.981x \pm 1.409$  and  $y = 0.408x \pm 1.181$  for the increase of NPSH and GSH, respectively.

the amount of glutathione was determined specifically by the glyoxalase assay using the technique of Klotzsch and Bergmeyer<sup>4</sup>. In this case, the standard error of a single determination was 5.3 per cent of the mean.

In 13 separate tests, the concentration of cysteamine in the incubation medium was varied between 0.7 and 6.3 mM. The actual concentration of the compound was, in each case, established at the end of the incubation period. Fig. 1 illustrates the NPSH- and GSH-levels of the treated cells in relation to the respective controls. It can be seen that NPSH in the cells increased in a direct relationship to the amount of cysteamine in the medium, an almost ten-fold increase of the cysteamine concentration being associated with a nearly two-fold increase of cellular NPSH. The increase in NPSH was, in part, due to an increase of GSH which was also directly related to the cysteamine concentration. On the average, 37 per cent of the NPSH increase was due to a rise of the GSH-level. In the cells not exposed to cysteamine, practically the whole NPSH content,  $2.48 \pm 0.08 \times 10^{-8}$  μmoles/cell (mean  $\pm$  S.E. calculated from the values of the controls), consisted of GSH, which totalled  $2.42 \pm 0.11 \times 10^{-8}$  μmoles/cell.

It is reasonable to assume that incorporated cysteamine or some sulphhydryl-containing product of this compound of low molecular weight accounts for the non-GSH component of NPSH in the treated cells. No simple explanation can be offered for the increased GSH content. New formation of GSH in the cells during the incubation period in the amounts recorded would require an extraordinarily accelerated rate of synthesis, the feasibility of which is unknown.

Possible reduction of oxidized glutathione (GSSG), known to be affected by cysteamine<sup>5</sup>, could explain a part of but not the whole GSH increase. The conclusion is based on results obtained in assays performed by the method of Klotzsch and Bergmeyer<sup>4</sup> with eight different samples of our material. The results showed a GSSG content of  $0.200 \pm 0.060 \times 10^{-8}$  μmoles/cell. This amount equalled not more than 16 per cent of the total GSH content and was in agreement with measurements of the acid soluble disulphides in non-neoplastic material<sup>6</sup>. Thus, even if wholly reduced, it cannot account for more than an increase of the cellular GSH content by a factor of 1.16 on the average.

Mixed disulphides between glutathione and protein (GSSP) can be considered more likely as the possible source of the increased GSH content. The occurrence of such disulphides in our cell material is strongly suggested by the results of recent experiments designed to test this possibility. In these experiments, cells from 2 ml. ascitic fluid were treated with 2 vol. of 6 per

cent perchloric acid for 1 h, and the resulting precipitate was washed 3 times with 10 volumes of the acid. No measurable GSH or GSSG was detected in the last wash fluid. The disulphide bonds of the washed precipitate were then reduced by treatment with sodium borohydride essentially according to the technique of Moore *et al.*<sup>7</sup>. The reaction was carried out by dissolving the precipitate in 4 ml. of a 0.5 per cent solution of sodium lauryl sulphate and sodium borohydride at a temperature of 40° C. After treatment for 1 h, the excess sodium borohydride was destroyed by lowering the pH of the solution to 7 by means of 1 N hydrochloric acid. The proteins were then again precipitated with perchloric acid. After centrifuging, GSH, conceivably released from the proteins, could be demonstrated in the supernatant in amounts corresponding to about  $2 \times 10^{-8}$  μmoles/cell.

Mixed disulphides between cysteamine and protein (CSSP) have been demonstrated by Eldjarn and Pihl<sup>10</sup>. Possible release of GSH from GSSP, in association with the formation of CSSP, might explain the observed increase of intracellular GSH, as well as the occurrence of CSSP following cysteamine treatment of cells. The formation of CSSP resulting in a temporary blockage of vital sulphhydryl groups has been regarded as a possible mechanism for the radioprotective action of cysteamine. Release of intracellular GSH can also be considered as a significant factor in the radiation protection afforded by cysteamine treatment. This consideration is based on the direct correlation between cellular NPSH content and radioresistance found in experiments with different clones derived from a common cell population<sup>8,11</sup>, and with cells treated with varying doses of cysteamine<sup>1,2</sup>. GSH may protect by functioning as a scavenger of radiation induced free radicals, and as a specific agent for the elimination of radiation generated hydrogen peroxide via the glutathione peroxidase pathway<sup>12</sup>. If the idea that intracellular release of GSH affords radiation protection is accepted, it is reasonable to extend the search for potential radioprotectors to include compounds which can induce an increase of intracellular GSH.

### Reactivation of Radiation-killed *E. coli* with Ribonuclease

RIBONUCLEASE has been reported to influence the action of X-rays on *E. coli*<sup>1</sup>. This communication shows that the presence of ribonuclease during irradiation did not influence the percentage of survivors, but presence of ribonuclease after irradiation and during incubation at 37° C increased the survivor ratio to a very high value.

*E. coli* B cells were routinely grown in Difco nutrient broth, supplemented with 0.2 per cent sodium chloride. Cells were grown with continuous aeration from an overnight culture to reach a logarithmic phase of growth in nutrient broth. Solid media were prepared by addition of 1.5 per cent Difco agar to the foregoing liquid media. Cells were gathered on nutrient agar plates at suitable dilutions and plates exposed to X-rays or ultra-violet rays, as the case may be, for the different doses of exposures. The plates either contained the graded amounts of ribonuclease before the exposure dose or graded amounts of ribonuclease were added after the exposures. Incubation of the plates after exposure was carried out at 37° C for the usual period of 18 h. Comparison of the colonies developed in plates containing ribonuclease with those in plates having no ribonuclease gave the difference in surviving ratio due to the influence of ribonuclease.

X-rays used were 80 kV, 17 m.amp at the dose rate at the place of irradiation of 340 rads/sec without filtration and ultra-violet dose rate was 30 ergs/mm<sup>2</sup> sec. The total doses of both X-ray and ultra-violet ray were so selected as to give about 0.1 per cent survival ratio for the bacterial cells.

Fig. 1 shows the variation in the percentage of X-ray survivors due to incubation in presence of various quantities of ribonuclease on plate. Curve *a* is the case when the ribonuclease was added to the plate before irradiation and remained on it during the incubation period. Curve *b* is for the case when the ribonuclease was added immediately after irradiation but was not present during the time of irradiation. Incubation of the plates continued in presence of the added amount of ribonuclease. The survivor percentage in the absence of ribonuclease was normalized to 100 and corresponding normalization with respect to this value for other cases of survivors in presence of various quantities of ribonuclease was done. Curve *a* shows that the saturation value of the increase in survivors reaches about twelve times in presence of 80 µg/ml. ribonuclease. Curve *b* shows that saturation value is as high as 45 times and is reached at 25 µg/ml. of ribonuclease concentration. Also the shapes of the curves are distinctly different; whereas in case of curve *a* the initial rise is slow, in case of curve *b* the rising part is very stiff.

When cells are exposed to X-rays in presence of ribonuclease, but freed from this immediately after irradiation and plated in absence of any ribonuclease, the number of survivors remains the same within the limits of experi-

Fig. 2. Influence of ribonuclease on the survival of *E. coli* B cells after irradiation.

mental error for all the quantities (not shown in figure).

Fig. 2 shows the variation in violet survivors due to the in various quantities of ribonuclease curves for the case when ribonuclease was added before irradiation or after irradiation.

The results clearly indicate that ribonuclease during the incubation period is necessary for the recovery of survivors. Thus ribonuclease is necessary for the recovery of survivors rather than of protection. The difference between curves *a* and *b* of Fig. 1 is due to the fact that ribonuclease is inactivated during the incubation period. The available quantity of ribonuclease is less in case of curve *a* resulting in a decreased saturation value of the increasing initial part. However, the difference in the results of the reactivation of the survivors after X-rays and ultra-violet rays is not so large. Whereas the level for X-rays is about 45 times, for ultra-violet rays it is only about 12 times. This difference only highlights the difference in the action of X-rays and ultra-violet rays. Ultra-violet rays are known to produce thymine dimers<sup>1</sup>, which are repairable only by an excision-repair mechanism. For X-rays, there must be some other mechanism by which when affected can induce a repair mechanism. It has been observed that the effect of ribonuclease is to break down (ribosomal) to 4 S (soluble) RNA. It is conjectured only how this break down helps the cell to recover from the radiation damage. But this much is obvious from the results of the experiment for ultra-violet damage as that.

## Cell Cycle of Mouse Embryo Fibroblasts in Continuous Culture

THE cell cycle in proliferating adult animals commonly takes the form of a continuous cycle. The synthetic period (*S*) is fairly constant in duration and the post-DNA synthetic period (*G<sub>2</sub>*) is also fairly constant in duration. Most of the variations in the duration of the pre-DNA synthetic period (*G<sub>1</sub>*) are known<sup>1</sup>. Among the variations yet reported are those found in

Fig. 1. Influence of ribonuclease on the X-ray inactivation of *E. coli* B cells. *a*, ribonuclease added before irradiation; *b*, ribonuclease added after irradiation.

rat gut (8.2-8.4 h) (ref. 2), in the chronically irradiated mouse gut (~8 h) (refs. 3 and 4) and in the neural tube of mouse embryos at 10 days gestation (probably ~8.5 h; ref. 5).

Embryonic tissue is one of the most rapidly proliferating cell systems known in mammals. In the present investigation the cell cycle was studied in the tip of the tail of the embryonic mouse at the 12th-13th day of gestation both in control animals and in animals that had been exposed to 5 days of continuous gamma irradiation at 50 rads/day. The tip of the tail of the embryonic mouse during the period is growing very rapidly. It behaves somewhat like a root tip. There is an area of high cell division at the tip and, as additional cells are produced, somites are formed behind the tip. Cell division, however, is not restricted to the tip as in root tips, and divisions continue in the newly differentiated somites.

Pregnant *Strong A* female mice at the 12th day of gestation as judged by vaginal plugs were injected with 50  $\mu$ Ci  $^3$ H-thymidine in normal saline (1.0 c./mM, Radiochemical Centre, Amersham) and killed at various intervals up to 20.5 h after injection. Embryos were fixed in 1:3 acetic-alcohol and stained *in toto* by the Feulgen method. Squash preparations of the tip of the embryonic tail were made in 45 per cent acetic acid. The cover glasses were removed by the dry-ice method and autoradiographs were made with Ilford 'K-5' liquid emulsion. Exposures were for 3 months. The irradiated mice were placed in the caesium-137 unit\* on the 7th day of gestation at a dose rate of 50 rads/day. Irradiation was continuous except for 0.5 h servicing intervals every other day. The irradiated mice were treated with  $^3$ H-thymidine and processed identically with the controls. Irradiation continued until they were killed. Autoradiographs were scored for labelled mitoses. From 3 to 12 tail tips were scored per pregnant female. At least 40 mitoses were observed in each tail tip and the results were summed for all the tail tips from one pregnant female.

Labelled mitoses for both the control and irradiated series are shown in Fig. 1. The data from the irradiated animals are very similar to those from the control group. The results indicate that this embryonic tissue has one of the shortest cycle times yet observed in mammals, about 8.5 h. An analysis of the cycle for both irradiated and control series indicates an *S* period of 6.5 h, a  $G_2 + M/2$  of 1 h and a  $G_1 + M/2$  of 1 h, where *M* represents the duration of mitosis.

Several reports show that continuous exposure of proliferating tissue to gamma-rays will shorten or lengthen the cell cycle. In plant root tips the cycle may be lengthened<sup>6,7</sup>, whereas in the intestinal crypt cells of the mouse the cycle is shortened<sup>8,9</sup>. The conditions and times of exposure were similar in this experiment to our previous work with intestinal crypt cells<sup>4</sup>. There, after a 5-day exposure of male *Strong A* mice to 50 rads/day, we found evidence of a shortened  $G_1$  period in the crypt cells of the

ileum. Here, on the other hand, in embryonic major change in the cell cycle can be detected because the cell cycle is already as short as possible given environmental conditions. Further studies of proliferating tissues are necessary before a statement can be made about the effect of ionizing radiation on the cell cycle in the mouse.

This investigation was supported in part by a doctoral fellowship (OF-8465) and by grant G of the U.S. Public Health Service.

## BIOLOGY

### Induction of Chromosome Aberrations by Aflatoxin

In 1960 an outbreak of 'Turkey X' disease in turkeys in Britain. This outbreak was traced to effects of groundnut meal which formed part of the food<sup>1,2</sup>.

The toxic factors (which are now called aflatoxins) were found to be metabolites of *Aspergillus flavus*<sup>3</sup>, which is a common contaminant of groundnuts, groundnut cake and meal, and maize<sup>4,5</sup> and other foodstuffs. Aflatoxin was found in the milk of cows fed on rations of groundnut meal<sup>6</sup>.

Recent work has shown that aflatoxin is the most active known liver carcinogen for man and also induces local tumours when injected in the livers of rats<sup>7</sup>.

Histological examinations have been made of induced tumours in rats, but, so far as is known, no previous attempts have been made to investigate the action of aflatoxin on chromosomes.

The present experiments were carried out on seedlings of *Vicia faba* (Sutton's prolific). The aflatoxin solution used consisted of 2  $\mu$ g aflatoxin B<sub>1</sub>, 56.4 per cent aflatoxin G<sub>1</sub>, and aflatoxin G<sub>2</sub> were present in small amounts. The aflatoxin was dissolved in alcohol. This solution was then added to water, and the alcohol was removed by evaporation.

Control experiments with roots treated with water which had been mixed with alcohol and then evaporated showed that there were no chromosome aberrations induced by any traces of alcohol which may have remained after evaporation.

Roots were treated under two experimental conditions. Half the roots were immersed for 3 h in 6.7  $\times 10^{-4}$  M aflatoxin at pH 5.8 and at 21°C. The other half were treated in water for 3 h. After this treatment all the roots in both experiments were returned to the bean culture jar and grew in water.

Fig. 1. Labelled mitoses in the tip of the tail of the embryonic mouse at 12-13 days gestation. O, Controls; ●, irradiated with 50 rads/day between days 7 and 12 of gestation. There is no major difference between the two series.

Table 1. ABNORMAL ANAPHASES IN ROOTS FIXED AT VARIOUS TIMES AFTER TREATMENT FOR 3 H IN AFLATOXIN

Fixation Water	Times (h)	3	6	12	24	30	48	72
	No. of anaphases examined	200	200	200	200	200	200	200
	% abnormal anaphases	0	2	0	1	0.5	1	1
Aflatoxin	No. of anaphases examined	195*	200	200	59*	59*	200	200
	% abnormal anaphases	41.5†	11.5†	2.5	16.9	30.7	25.5	2

\* The low mitotic index at these times reduced the available anaphases below the 100 per root normally examined.

† Roots at each of these times contained sticky chromosomes with bridges but few fragments.

At various intervals after treatment (timed from the beginning of the 3-h treatment) roots were fixed in 1:3 acetic alcohol. The fixation times were at 3, 6, 12, 24, 30, 48 and 72 h. The roots were then hardened in absolute alcohol and stored in 70 per cent alcohol.

Roots were hydrolysed at 20° C in 5 N hydrochloric acid for 40 min and stained in leucobasic fuchsin and squashed. Two roots were analysed from each treatment at each fixation time. Anaphases showing fragments and bridges were scored as abnormal. The results are shown in Table 1.

There is a highly significant ( $P < 0.001$ ) increase in the number of abnormal anaphases following treatment with aflatoxin. Most of the abnormalities consisted of chromosome fragments with occasional bridges, except at 3 h where both roots, and 6 h where one root, showed stickiness and many bridges. There was a considerable inhibition of mitosis (especially at 24 and 30 h) followed by a peak of divisions at 48 h.

Further experiments are in progress to compare the action of aflatoxin with that of well-known radiomimetic substances. It is also hoped to obtain samples of the separate aflatoxins for experiments.

Butler and Barnes<sup>1</sup> and other authors<sup>2-4</sup> have discussed the possible hazards of aflatoxin to man. These authors have directed attention to the possible part that fungal products may play in producing liver cancers in various parts of the world. So far there are no detailed investigations reported linking the occurrence of liver cancer with aflatoxin in humans. However, it is of interest that during an investigation into the induction of chromosome breaks in human blood cells in culture, being carried out in this laboratory, preliminary results have indicated that aflatoxin breaks human chromosomes<sup>11</sup>.

The aflatoxin used was a gift from the Tropical Products Institute, Department of Scientific and Industrial Research, to Prof. F. Dickens, of the Courtauld Institute, Middlesex Hospital, London, W.1.

*Note added in proof.* Recent experiments<sup>12</sup> have shown that aflatoxin treatment inhibits the synthesis of deoxyribonucleic acid from tritiated thymidine and inhibits mitosis, in cultures of human embryonic lung cell lines.

## Individualized Whistle Contours in Bottle-nosed Dolphins (*Tursiops truncatus*)

In 1953, Essapian<sup>1</sup> suggested that individual bottle-nosed dolphins, *Tursiops truncatus* (Montagu), may have distinctive notes which each dolphin can recognize. From his context, in using the word 'notes' Essapian referred to the whistle component of *Tursiops* phonation.

In spite of the extensive work that has been done on the vocalizations of this and related dolphin species, this approach to the whistles as suggested by Essapian apparently has received no further consideration. Rather, the accent has been on an attempt to attach a particular whistle to a definite situation<sup>2</sup>. It has even been theorized that the various whistles could conceivably constitute a language<sup>3</sup>.

In the course of investigation relating to other aspects of cetacean behaviour, we recorded the vocalizations of five freshly captured *T. truncatus*, consisting of two adult females, one adult male and two sub-adult males. Vocalizations were audited for approximately three weeks following capture and in a great variety of circumstances. Our tapes show that with this group of animals, all taken from one wild school, each animal showed a clear tendency to emit the same whistle regardless of the situation. This becomes particularly clear when the tapes are slowed to 1/8 normal speed. The variety of situations to which they were exposed included isolation from the group (by which individual whistles were identified), feeding, entrance of divers into the tank, introduction of a strange dolphin into the tank, removal from a familiar tank to an unfamiliar one, and exposures to novel and sometimes disturbing stimuli including dead young from the same wild school. Although the whistle might vary slightly, the basic contour remained the same. The manner in which the whistle varied included number per minute, intensity, duration of the one whistle, and the abrupt breaking off of a whistle which had begun to be emitted. These variable units are potentially capable of conveying much information. For example, under mildly stressful situations, the whistles increased in number and intensity. In very alarming situations, the whistles ceased for a few minutes. The basic information transmitted, however, would be the identity of the animal doing the whistling.

The five predominant whistles for the five animals were clearly distinctive from each other at 1/8 speed. They consisted of the following whistles which can be compared with chart I of the whistle contours of *T. truncatus* as catalogued by Dreher and Evans<sup>4</sup>. Contour 1, corresponding to Dreher and Evans's contour 1, was a sharply rising single up-sweep, and was emitted in a series of one to nine whistles. Contour 2, a falling inflexion, corresponds with Dreher and Evans's contour 9. In our animal, this had a break toward the lower end and was never emitted more than twice in series, and usually only once. The third contour, a single unbroken up-and-down sweep, is the same as contour 3 of Dreher and Evans and was emitted almost constantly by one of the young males. It was made in series of 1-7 quick whistles and at 1/8 speed had a distinctive series of breaks in both rising and falling, somewhat resembling a scale as practised by a singer. Contour 4, corresponding to Dreher and Evans's contours 6 and 15, began with a falling inflexion, then rose and fell at least once. The rising and falling inflexions were sometimes continued without break for up to four more warbles. Our contour 5 somewhat resembles our contour 4, with the exception that it begins with a rising rather than a falling contour, and may warble from twice (Dreher and Evans's contour 5) up to five complete and unbroken warbles similar to contour 14 as presented by Dreher and Evans, which shows four complete warbles.

The most conclusive evidence which we can present regarding the individualization of these whistles is that, on being placed together, when one animal begins whist-

ling, others frequently follow suit resulting in a confused overlay. However, at slow speeds the individual whistles can be isolated. During these whistle sessions the individual contours were retained, and as they overlapped each other it was obvious that each animal was making its individual whistle. As our contours 4 and 5 varied only in the initial rise or fall of the warble, only the overlaid whistles of these two animals proved that they were distinctive and not variations of one contour.

On the basis of these observations we do not intend to state arbitrarily that a single animal has a vocabulary of a single somewhat variable whistle contour. However, this distinctive whistle occupied much more than 90 per cent of the total whistle vocabulary of any one animal during this three-week period following capture. Very rarely, however, an unfamiliar whistle was recorded. We do wish to point out, however, that our work to this point indicates a definite tendency toward an individualized whistle. Further investigation of this point is contemplated in the immediate future.

The whistle constitutes only one of the many phonations emitted by *T. truncatus*. Squeals, chirps, squeaks, squawks, barks, yelps, grating sounds, and echo-location bursts are common ones. Although some of these have been clearly shown to be used for echo-location<sup>4</sup>, others such as the squawk, even though containing very rapid pulses, may be indicative of the emotional state of the animal and not an echo-location device. Much work remains to be done in analysing these sounds in relation to behaviour.

Support for this work was received through grants from the U.S. National Institute of Mental Health (MH-07509-01) and the U.S. National Science Foundation (GB-1189). We thank William E. Evans of the University of California, Los Angeles, and William N. Sutherland of the Lockheed-California Company for assistance with the recording equipment, and J. B. Siebenaler of Florida's Gulfarium, Fort Walton Beach, for help with the capture and maintenance of the animals.

## Correlations between the Architecture of Shoots and the Particular Fragments of them found as Fossils

OBSERVATIONS were made on plausibly-coniferous fossil shoots in silicified floras from arid southern central Australia. Such floras are found in an indurated siliceous matrix superficially resembling siltstone<sup>1</sup>, but occurring as eroded stones on various landsurfaces. The fossils, loosely oriented according to apparent bedding planes, are undistorted natural moulds of very high fidelity, often carrying details of surface morphology down to the microscopic dimensions of cell outline. They are not well expressed on fresh fracture faces, but only on weathered faces, by differential erosion. Of the plant debris fossilized within the matrix, one might expect the array presented at the surface of the eroded stony fragments to be dictated by chance, at the vagaries of erosion and weathering. However, the particular kind of fragment (branched or not, terminal or not, etc.) was found to be correlated with the architecture (and hence with the systematic status) of the shoot, despite fragmentation.

Correlations between characters of presentation and characters of shoot architecture were sought among 76 fossil shoots (of 21 different kinds) on characters including, on one hand, length of fossil, whether branched or not, and whether terminal or not, and on the other whether phyllotaxis was spiral, decussate, etc. Results of contingency comparisons between some of these features are given in Table 1.

Fig. 1. A-D, *Palenochia minor*. A, left  $M_1$ , U.S.N.M. No. 9590. B, right  $P_4$ , A.M.N.H. No. 35443. C, labial part left  $M_2$  (not  $M_2$  as stated in ref. 5), U.S.N.M. No. 9595. D, labial view left  $M_2$ , U.S.N.M. No. 9595. E-F, *McKennaetherium laticum*, left  $M_1$ - $M_3$ , type specimen. E, occlusal view. F, labial and slightly anterior view. Areas with X are broken, dotted areas are wear facets, and dashed lines are concavities ( $\times 15$ )

mandible fragment with  $M_1$ - $M_3$  from Gidley Quarry<sup>5</sup>, Lebo Formation, Crazy Mountain Field, Montana.

Diagnosis: Most closely similar to *Palaschthon* and *Palenochia*. The lower molars differ from both these genera as follows: teeth relatively longer anteroposteriorly (except for the specialized  $M_2$  of *Palaschthon*); lateral walls of teeth more vertical; trigonid somewhat lower; posterior wall of trigonid somewhat less vertical; crista obliqua not extending up posterior wall of trigonid (also true in some specimens of *Palenochia*); talonid basin shallower; hypoconulid distinct on  $M_1$ - $M_3$ ; deepest point of talonid basin central;  $M_2$  shorter than  $M_1$ . Additionally differing from *Palaschthon* as follows: talonid narrower than trigonid; paraconid more distinct from parolophid and projecting more anteriorly; labial cingulum virtually absent; accessory protolophid absent; metaconid less bulbous; hypoconid relatively lower; no incipient third lobe on  $M_2$ ; hypoconulid single on  $M_2$ ; entoconid no more basin central;  $M_2$  shorter than  $M_1$ . Additionally differing from *Palenochia* as follows: parolophid less anterior; direct ridge from paraconid to protoconid absent; metaconid less posterior; base of enamel on labial side of trigonid rising much less steeply; hypoconid relatively lower; hypoconulid of  $M_1$ - $M_3$  somewhat lingual; hypoconulid lobe smaller but hypoconulid larger on  $M_2$ .

Table 1. MEASUREMENTS OF *McKennaetherium laticum*, TYPE SPECIMEN

	Length (mm)	Trigonid width (mm)	Talonid width (mm)
$M_1$	1.7	1.2	1.1
$M_2$	1.6	1.2	1.0
$M_3$	1.5	1.0	0.8

The genus is named for Malcolm C. McKenna; the specific name is a Latin word meaning pleasing.

Examination of specimens of *Palenochia* and *Palaschthon* has shown the presence in each genus of a previously unreported anterior tooth. In *Palenochia minor*, the alveoli of A.M.N.H. No. 35449 show that there are five antemolar teeth, the same number and presumably with the same homologies as those of *Paromomys*. In *Paromomys*  $P_4$  is two-rooted; in *Palenochia* it is one- or possibly two-rooted. The incisor of *Palenochia* is not particularly enlarged. In *Palaschthon alticuspis*, A.M.N.H. Nos. 35478 and 35489 have complete sets of alveoli, which indicate an

additional one-rooted tooth behind the moderately enlarged incisor. This additional tooth is probably  $I_2$ , although it could be  $P_1$ . The specimens used by Simpson<sup>6</sup> do not contradict the revised formulae. The lower dental formula of *Palenochia* and *Paromomys* is then, most probably,  $I1, O1, P3, M3$ , and of *Palaschthon*  $I2, O1, P3, M3$ . These genera are therefore not as aberrant as was previously thought.

I take this opportunity to present drawings of the upper dentition of *Palenochia minor* (Fig. 1 A-D). The figure given by Gidley<sup>5</sup> and copied by Simpson<sup>6</sup> is inaccurate.

*McKennaetherium*, *Palenochia*, *Palaschthon*, and probably *Plasiolestes* form a group of closely related genera that may provisionally be placed in the Paromomyidae pending a clarification of early prosimian interrelationships. The late Palaeocene genus *Navajovius* is generally similar to this group (its  $M_2$  is especially similar to that of *Palenochia*), but for the most part its similarities are confined to primitive characters. *McKennaetherium* and *Navajovius* are, in most of their known characters, the two most primitive primates as determined by comparison with possible near ancestors in the Insectivora<sup>7</sup>. Primitive erinaceoids, such as *Leptaecodon tener*, and leptictids seem the most likely near ancestors of the primates<sup>8,9</sup>, although this is uncertain. This conclusion implies that semimolariform fourth premolars may be primitive in primates, as further comparisons suggest even for the Eutheria as a whole<sup>10</sup>. The Microsypidae, placed possibly correctly in the Primates by McKenna<sup>3</sup> and Simons<sup>11</sup>, are unknown before the Eocene but at that time are not especially similar to the genera mentioned in this paragraph.

I thank Dr. M. C. McKenna for help in various ways, and Dr. C. L. Gaxin for the loan of U.S.N.M. specimens.

## Loss of Suberin from Bark tissue rotted by *Armillaria mellea*

SUBERIZED tissue has for a long time been regarded as among the most resistant of plant tissues to fungal decay. Cork can be virtually immune from breakdown<sup>1,2</sup>, and the production of cork barriers is a common host reaction to fungal infection<sup>3</sup>. Nevertheless, there can be little doubt that suberin must eventually be degraded by microorganisms in the soil and litter; similarly, it is known that several fungi are capable of penetrating suberized barriers. Among these is *Armillaria mellea*, which was shown by Thomas<sup>4</sup> to be able to penetrate directly through the bark of host roots. Although this penetration was largely mechanical, Thomas reported some degradation of the cork layers in advance of the fungal hyphae. This suggestion of enzymatic breakdown of the cork layers has been largely discounted by later authors<sup>5,6</sup>.

Recent work here has, however, shown that the suberin content of bark tissue shows a marked decrease during rotting of the tissue by *A. mellea*. Ground bark tissue from the roots of *Brachystegia spiciformis* was extracted with ethanol, water and 5 per cent  $\text{Na}_2\text{SO}_3$  successively, and then the suberin, holocellulose and lignin contents

# What do you do with data?

As makers of a range of rugged, reliable, economical and flexible Data and Instrumentation Recording equipment, we know a thousand and one ways of using magnetic recording for data acquisition, storage and analysis—in aeronautics, medicine, industry and university research work. Magnetic recording provides a wide range of band widths and high information packing density. Data expansion and contraction facilities are available which are not possessed by other forms of data acquisition. Thermionic equipment is the lowest priced range of digital and analogue recorders for research—we designed it on the unit principle for complete flexibility of use and we're sure it will answer your data handling problems.

You tell us!

Tell us what your particular research requirements are and we'll show you how THERMIONIC Data Recording Systems can meet them quickly, simply, cheaply. Drop a line to us today.

## progress in service 1915 to 1965

Some aspects of service developed over the last half-century are reflected by the BDH catalogue of 1965. This contains a complete range of modern laboratory reagents. Specifications of purity are introduced liberally; formulae, molecular weights, liquid densities are given throughout. A long list of BDH technical publications is prominent. Reagents and groups of reagents appear for specialised laboratory procedures. Much of the catalogue is occupied by materials serving the newer developments in laboratory methods.

From the catalogue alone other aspects of BDH service today are less evident. BDH has set new standards in informative labelling. Packaging has been revolutionised. To secure speedy and efficient packaging and distribution a million pounds has been spent on new BDH warehouses at Poole; and comprehensive stocks are established locally in the main industrial centres. Throughout the country regular van services deliver several thousand orders every week.

New reagents which promise to be of interest to laboratories and additions to the rapidly extending range of BDH biochemical materials, as well as new BDH publications, are fully described in a monthly leaflet which has been published since 1953. Information on products and laboratory methods is available from the analytical and technical service departments at Poole; these, and the various BDH production and development departments, can equally provide information and advice where pure chemicals are required industrially to meet new technological demands.

BDH seeks to provide effective service in production, packaging and delivery, and in general and specific technical information. It invites you to make full use of its services in your own laboratories.

Fig. 1. Changes in composition of bark tissue due to rotting by *A. mellea*

were estimated, both before and after rotting by *A. mellea*. The suberin was estimated by the iodine-complexing method developed by Zetsche, Oholatnikov and Scherz<sup>7</sup> and the holocellulose and lignin separated by hydrolysis of the carbohydrate with 72 per cent  $H_2SO_4$ . Fig. 1 shows the changes in the content of these three fractions during rotting of the tissue by *A. mellea* over a period of ten months. During this period, the tissue lost more than 25 per cent of its dry weight; the holocellulose content had decreased by 14 per cent, the lignin by 9 per cent. The suberin content, on the other hand, had dropped from 10.8 per cent (of the original dry weight) to 4.7 per cent—a loss of 59 per cent of the original content.

These results indicate that suberin is lost from bark tissue during rotting by *A. mellea* and suggest the possibility of enzymatic breakdown of this substance by the fungus. It is hoped to be able to pursue this matter further, both with a larger range of fungi, and by investigation of the breakdown products of suberin degradation.

This work was supported by a grant from the Rockefeller Foundation.

## ENTOMOLOGY

### Influence of Radiation on Ovarian Maturation and Histolysis of Pupal Fat Body in Diptera

In *Calliphora* the medial neurosecretory cells of the brain are necessary for ovarian maturation<sup>1</sup>. They seem to act partly by inducing the release of a gonadotrophic hormone from the corpus allatum and to regulate the storage and mobilization of nutrients in the adult fat-body. Doane studied the interaction of ovary, corpus allatum and adult fat-body in mutant (female sterile (2) adipose) *Drosophila*<sup>2</sup> and concluded that the ovary itself, in developing under hormonal stimulus from the corpus allatum, mobilizes reserves in the adult fat-body by secreting a second hormone.

This system of developing organ (ovary), nutrient source (adult fat-body) and controlling mechanism (neurosecretory cells and corpus allatum) contains a second nutrient source variously called the 'larval fat-body'<sup>3</sup>,

'products of histolysis'<sup>3</sup> and 'pupal fat-body'<sup>4</sup>. It is a tissue left over from the pupal stage which rapidly disappears in normal flies as the ovaries begin to develop. Probably it is only a supplementary source of ovarian nutrients, because dietary deficiency in some adult Diptera both inhibits ovarian development and retards histolysis of the pupal fat-body<sup>4,5</sup>.

How is this histolysis controlled? Is it accomplished by direct action of the juvenile hormone and does maturation of the ovaries wait on this action? Or does the secretion of the corpus allatum stimulate the ovary, causing it to demand histolysis of the fat-body? Further questions are raised by the observation that, in Queensland fruit-fly *Dacus tryoni* Frogg (Diptera, Tryptetidae), doses of  $\gamma$ -radiation exceeding 4,000 rads also suppress ovarian maturation and delay histolysis of the pupal fat-body. Is this due to: (a) direct damage to the ovary and hence reduced 'demand' on the fat-body, or (b) damage to the brain or corpus allatum which prevents them from producing the gonadotrophic hormone, or (c) interference with a hypothetical mechanism by which the ovary controls the secretory activity of the corpus allatum, or (d) blockage of the system by damage at more than one point?

In the following experiments we tried to eliminate some of these alternatives. If (b) is correct, irradiation of the head should prevent ovarian maturation. We gave the following treatments to four randomly selected groups of pupae *Dacus tryoni*, using pupae 6–8 days old and, for convenience, a 120-kV source of filtered X-rays instead of  $\gamma$ -rays. The pupae were exposed on a 'Perspex' plate to a dose in air of 8,000 rads, as follows: Group A: control, not irradiated; Group B: whole body irradiated; Group C: anterior third of body irradiated; Group D: posterior third of body irradiated. The unirradiated portions of pupae in Groups C and D were shielded by lead blocks 1.2 cm thick. Scattering into the shielded parts seemed to be negligible when tested with X-ray plates. When adult flies emerged, they were provided with water, sucrose and enzymatic hydrolysate of yeast and kept at 25° C in a photoperiod of 15–16 h. After 5 weeks, the females were dissected. Ovarian development was scored on a subjective scale from I to IV. Stage I ovaries showed no apparent development over the ovaries of newly emerged flies and Stage IV was identified by the presence of mature eggs. The presence or absence of pupal fat-body was also recorded. The results are shown in Table 1.

Table 1

Group	Treatment	Nos. in each stage of ovarian development (I–IV) and Nos. with pupal fat-body (pfb)							
		I	II	III	IV	pfb	pfb	pfb	pfb
A	Control	0	0	0	0	0	54	0	0
B	Whole body irradiated	45	Not recorded	0	Not recorded	0	Not recorded	0	Not recorded
C	Anterior third irradiated	8	0	4	0	1	21	0	0
D	Posterior third irradiated	29	19	2	0	0	1	1	1

The difference in ovarian maturation between Groups A and B does not call for statistical analysis. If we pool the data from animals in Groups C and D under the headings Mature (Stage IV) and Immature (Stages I–III), they are significantly different ( $\chi^2 = 7.1$ ,  $P < 0.01$ ) and they also differ significantly ( $\chi^2 = 22.2$ ,  $P < 0.001$ ) in the proportion of animals which have histolysed their pupal fat-bodies. The ovaries of eight animals in Group C remained in Stage I and in seven animals of Group D they went on to Stage IV probably because of scattered radiation or variation in alignment under the lead shield.

Obviously irradiation does not directly prevent secretion by the corpus allatum and it apparently acts directly on some abdominal organ. Doane<sup>2</sup> suggested that the ovary itself may influence the secretory activity of the corpus allatum, and our results could mean that radiation blocks some stimulus from the abdomen, thus indirectly preventing ovarian development.

To test this hypothesis we applied farnesyl methyl ether, which mimics the gonadotrophic action of the juvenile hormones<sup>6</sup>, to the abdomens of newly emerged female flies which had been given a dose of 4,000 rads  $\gamma$ -radiation on the eighth day of pupal life. The farnesyl methyl ether was mixed with alumina dust to prevent it from spreading over the cuticle and perhaps to assist its entry into the haemocoel. The dose (12  $\mu$ g mixed with 15  $\mu$ g of alumina) was made large enough to induce marked muscular twitching in the legs of the recipients. Fifty-eight out of 132 treated females survived for 5 weeks but none showed ovarian development. This negative result suggests that the irradiated ovary may be incapable of responding to the gonadotrophic hormone from the corpus allatum, but tells us nothing about a possible stimulatory action on the corpus allatum by the ovary.

The histolysis of pupal fat-body seems to be partly dependent on ovarian maturation. But in these and more extended observations, irradiated flies lost their pupal fat-body slowly even though the ovaries did not develop. Presumably other demands cause a slow histolysis even in the absence of ovarian development, whether this is inhibited by radiation or by nutritional deficiencies in the adult diet<sup>4,5</sup>. These results suggest that radiation does not act hormonally and support the contention of La Chance and Bruns that it directly damages the nurse cells of the ovary<sup>7</sup>. This in turn probably reduces demand on the pupal fat-body and delays its histolysis.

We thank Prof. H. G. Andrewartha and Dr. E. M. Arnold for their advice. Samples of farnesyl methyl ether were given by Dr. J. Fellig of Hoffmann-La Roche Inc., and Mr. F. Hampshire of Union Carbide Australia, Ltd. Methods of applying farnesyl methyl ether were suggested by Prof. A. F. O'Farrell and Prof. A. Stock. The work was carried out in the Zoology Department, University of Sydney.

## MICROBIOLOGY

### Growth Inhibition of *Escherichia coli* by some Basic Proteins prepared from the Same Strain

PONTECORVO<sup>1</sup> in his Leeuwenhoek lecture to the Royal Society said that "histones are characteristic intranuclear proteins in search of employment". Other workers have suggested that histones could be concerned with the regulation of RNA synthesis<sup>2,3</sup>. The findings of Gurley *et al.*<sup>4</sup> were more specific. They found that in a cell-free system DNA polymerase was inhibited by a lysine-rich histone fraction. Our own work points in the same direction. During a study of the cellular control of metabolism we isolated basic proteins of *Escherichia coli* and found that some of these preparations inhibited the organism from which the protein was isolated.

*E. coli* (NCTC 8196) was grown in 49 l. of Littauer and Kornberg's medium<sup>5</sup> for 4 h (end of logarithmic phase) with mechanical stirring and forced aeration at 37° C. The cells were collected in a Sharples centrifuge, and

stored deep-frozen until required. We isolated an acid-alcohol-soluble fraction by the method of Johns *et al.*<sup>6</sup>, recommended for the isolation of the arginine-rich fraction of histone from calf thymus. 50 g bacterial paste was homogenized with 350 ml. ethanol:water (70:30 v/v) in a Braun disintegrator (Shandon Ltd., London) with 50 g No. 12 Ballotini beads and continually cooled with CO<sub>2</sub> snow. The homogenate was centrifuged and the supernatant discarded. The deposit was washed once in the above solvent, and the supernatant again discarded. The deposit was then taken up in 100 ml. ethanol:N.HCl:water (70:25:5 v/v), transferred to a ball mill, and extracted at 1° for 20 h. After centrifuging, the deposit was re-extracted in 50 ml. acid ethanol for 4 h at 4° and centrifuged, and the deposit was re-extracted for a further 2 h with 50 ml. solvent. The precipitate was discarded. The supernatants were combined and dialysed three times for 4 h at 4° against 300 ml. ethanol. The precipitate which forms during dialysis was collected by centrifugation, washed with ethanol, then with acetone, and dried under vacuum.

We also isolated a perchloric-acid-soluble fraction by the method of Johns and Butler<sup>7</sup> recommended for the isolation of the lysine-rich fraction from calf thymus. 50 g of *E. coli* paste was homogenized with 400 ml. 5 per cent v/v of 0.76N HClO<sub>4</sub> in a Braun disintegrator, with 50 g No. 12 Ballotini beads, and continually cooled with CO<sub>2</sub> snow. After centrifuging at 1100 g for 10 min, the deposit was re-extracted in 100 ml. 5 per cent HClO<sub>4</sub>. The combined supernatants were clarified through a No. 4 sinter and trichloroacetic acid was added to the clear extract to bring the final concentration to 12 per cent (0.74 M). After standing overnight at 4° the precipitate was removed by centrifuging. The sediment was dissolved in 100 ml. ethanol and concentrated HCl (1 ml.) was added, followed by 50 ml. acetone. The white precipitate formed was washed three times with acetone and dried under vacuum.

The effect on the growth rate of *E. coli* was followed by diluting an overnight culture 1/1000 in Littauer and Kornberg's medium to which different concentrations of the preparations redissolved in distilled water were added. The growth of the organism was followed by measuring the increase in optical density at 580 m $\mu$  for 8 h.

The fraction soluble in perchloric acid did not increase or reduce the rate of growth of *E. coli* at final concentrations of 200  $\mu$ g/ml.

The acid-alcohol-soluble fraction gave variable results. This preparation was repeated 17 times; 3 preparations were 'active' because they were inhibitory to growth; 14 preparations were 'inactive'.

The effect of the 'active' preparation is shown in Fig. 1. Growth inhibition was proportional to the concentration used: 40  $\mu$ g/ml. was partially inhibitory and 80  $\mu$ g/ml. was completely inhibitory. Inactive preparations gave curves which were indistinguishable from the control.

Fig. 1 Graded response assay of 'active' preparation: —●—, 80  $\mu$ g/ml.; —○—, 60  $\mu$ g/ml.; —□—, 40  $\mu$ g/ml.; - - - - - , control

Fig. 2. Polyacrylamide-gel electrophoretic patterns of acid-alcohol-soluble fractions of *Escherichia coli*.

These active and inactive preparations were examined by electrophoresis in polyacrylamide gel after the method of Reisfeld *et al.*<sup>6</sup> The gels were made up in potassium hydroxide/glacial acetic acid (pH 4.3) and they were run for 2 or 4 h. Fig. 2 shows that the 'active' preparations have a thick band of fast-moving component which is missing in the 'inactive' preparations. The latter, however, contains bands of slow-moving material missing in the 'active' preparation. The exact nature of the bands is not yet known and we cannot explain why some preparations should be active and others inactive. Activity most probably resides in the fast-moving component missing from the 'inactive' preparations, but it is also possible that the slow-moving bands which are present only in the 'inactive' material antagonize the inhibitory activity. Although only 3 of the 17 preparations were 'active' the interest of this work is that we have obtained at least some preparations which were inhibitory to the growth of cells of the strain from which they were isolated. It could be, therefore, that in the growing cell also such proteins are concerned with regulation of growth.

We thank Dr. P. Akroyd for carrying out the gel-electrophoresis.

## GENETICS

### Maleic Hydrazide, a Chemical Mutagen in *Drosophila melanogaster*

MALEIC hydrazide is one of the various reagents which induce breaks in the chromosomes of some plants at specific regions recognizable as heterochromatin<sup>1,2</sup>. It also inhibits growth in several species of plants, at least doubling the time taken to proceed through a complete mitotic cycle. Much of this delay in cell development has been explained by Evans and Scott<sup>3</sup> as due to severe depression in the rate of DNA synthesis. They also suggest that the aberrations are produced at the time of duplication, and that maleic hydrazide acts by interfering, in some way, with the normal process of duplication. It was also found by Compton<sup>4</sup> that it has a more pronounced effect on cell division in the roots than in the shoots. In view of its pronounced effects in plants, it was thought of interest to test this chemical for mutagenic action in *Drosophila*.

Males of a wild-type 'Oregon-K' (*Or-K*) strain, which has a spontaneous mutation rate of 0.3 per cent, were used. The standard Muller-5 test for sex-linked recessive lethals was used. The chemically treated medium was made up by stirring 0.4 per cent maleic hydrazide at 55° C into a standard medium. Seeding with live yeast was omitted. Flies reared on the standard medium started to emerge one day earlier than those reared on the chemically treated medium.

In a second experiment, one- to two-day-old males reared on the standard medium received abdominal injections of 0.7 per cent sodium chloride Ringer's solution containing 0.4 per cent maleic hydrazide.

The results are summarized in Table 1.

Table 1. FREQUENCY OF SEX-LINKED RECESSIVE LETHALS IN THE PROGENY OF MALES REARED ON FOOD CONTAINING 0.4 PER CENT MALEIC HYDRAZIDE

Brood	No. of sperm tested	No.	Lethals	%
1st	1,024	11		1.07
2nd	857	3		0.35
3rd	813	3		0.37

It is clear from Table 1 that the most advanced stage in the larval testis responded to maleic hydrazide. In the progeny of the injected males, it proved to be ineffective; only 12 mutations were produced in more than 3,000 chromosomes tested in four broods.

Since there is a possibility that maleic hydrazide, when given in the food, acts on auxocytes and since there are no auxocytes in the adult testis, this by itself could explain the lack of response for maleic hydrazide injected into adults.

## SOIL SCIENCE

### Extractable Aluminium in Steam-sterilized Soils

CHANGES in the chemical properties of steam-sterilized soils have been frequently reported<sup>1-3</sup>. The temporary increases in ammonia-nitrogen and readily available manganese have attracted particular attention.

In recent studies of manganese toxicity a high content of aluminium was observed in lettuce plants grown in steam-sterilized soil. The effect of steam-sterilization

on the extractable soil aluminium was therefore examined; N-ammonium acetate at pH 4.8 was chosen as the extractant, as used in some of the more recent investigations<sup>4-7</sup>.

Soil samples were taken from five locations at this Institute in November 1963 and again in March 1964. Sub-samples (200 g moist soil) contained in 250-ml. conical flasks, loosely plugged with cotton wool, were treated as follows: *A*, control—no treatment; *B*, steam-sterilized in an autoclave at 10 lb./sq. in. pressure for 30 min; *C*, as *B* with 0.3 per cent of CaCO<sub>3</sub> by weight mixed in before steaming; *D*, as *B* with 0.3 per cent of CaCO<sub>3</sub> by weight mixed in after steaming when the soil was cool.

All the flasks were sealed with 'Parafilm' to prevent drying, and after storing for three weeks at room temperature (18°–23° C) aluminium was extracted from the moist soil and determined by the aluminon method<sup>8</sup>.

In November 1963 only a single soil sample per location was analysed, thus limiting the statistical examination of the results. There was an increase in extractable aluminium in steamed soil, the mean values for treatments *A* and *B* being 23.2 and 35.8 p.p.m. aluminium respectively (based on oven-dry soil). Liming reduced the levels of aluminium to just below that of the unsteamed soil (*C*, 21.4; *D*, 20.6).

The results for samples taken in March 1964 are given in Table 1. A highly significant ( $P < 0.01$ ) increase in extractable aluminium due to steaming without liming was recorded for all samples. Liming either before or after steaming (*C* and *D*) decreased the content of extractable aluminium as compared with treatment *B*. Averaged over the five sampling locations, the combination of liming with steaming (*C* and *D*) resulted in a content of extractable aluminium below that of the untreated soils ( $P < 0.01$ ). The mean pH values for the four treatments are given in Table 1.

Table 1. ALUMINIUM (P.P.M. Al IN OVEN-DRYED SOIL) EXTRACTED WITH N-AMMONIUM ACETATE (pH 4.8) FROM SOIL SAMPLES TAKEN IN MARCH 1964

Body of the table	4.18
Soil means	2.07
Treatment means	1.87

\* L.S.D.—least significant difference.

The marked differences in aluminium extracted from the corresponding samples at the two dates probably reflect a seasonal change, but no definite conclusion can be drawn until the investigation has been continued over a longer period. Comparable seasonal changes in extractable aluminium have been reported by Plucknett and Sherman<sup>4</sup>.

Kelley and McGeorge<sup>9</sup> noted some increase in aluminium solubility in heated soils, but Robinson<sup>10</sup> and Lutrick<sup>11</sup> failed to observe any effect of steam-sterilization in their studies.

The injury to young plants often reported in steam-sterilized soils has been variously attributed to the accompanying increases in ammonia and soluble manganese. Excessive uptake of manganese certainly occurs in plants growing in some steamed soils, and gives rise to symptoms of manganese toxicity which can readily be reproduced in sand culture at high levels of this element. Not all cases of sterilization injury can be explained satisfactorily in terms of excess manganese or ammonia-nitrogen, however. The present results show appreciable increases in the content of extractable aluminium in steamed soils, and it is suggested that aluminium may be an important factor in sterilization injury. In this connexion it is of interest that young plants have been reported to be particularly vulnerable to an excess of aluminium<sup>12</sup>. The results may also help to explain the response of plants

to additional phosphate in cases of sterilization injury, even where the level of soil phosphate would normally be regarded as fully adequate for plant growth.

## Use of a Selective Cellulose Agar for Isolation of Soil Fungi

ADVANCES in soil microbiology have frequently been related to the development of selective isolation techniques. Such methods usually depend either on the provision of an energy source available only to a limited group of micro-organisms, or on the presence of an anti-microbial substance which allows a limited spectrum of micro-organisms to grow. Energy sources which have been studied by such methods include a range of monosaccharides, cellulose<sup>1,2</sup>, chitin<sup>3</sup>, xylan<sup>4</sup> and lignin<sup>5</sup>. The anti-microbial agents most widely used are the antibiotics, effective against various groups of soil organisms.

Concerning the isolation of fungi from the soil, it is clear that selective media have some advantages over 'non-selective' media, such as tap water agar and soil extract agar, but the exact nature of these advantages is often only imprecisely defined. Such definition requires detailed comparative studies, using the selective and non-selective agars in parallel.

During work on the rhizosphere of *Halimione portulacoides* (L.) Aell. in several salt marshes, such comparative information has been obtained concerning the value of cellulose agar prepared according to the method of Eggins and Pugh<sup>6</sup>. The soil plate technique of Warcup<sup>7</sup> was used on mud from two *Halimione* communities at Gibraltar Point, Lincolnshire, and one community at Parkgate, Cheshire, during the period October 1961 to July 1963. Fungi were recorded only as present or absent on the soil plates. In Table 1 the fungi listed were recorded as clearing the cellulose agar on more than 10 per cent of the soil plates in at least one of the three communities. These results are compared with those obtained for the same species using mud extract agar<sup>7</sup>. A modification of Warcup's technique, involving the subculturing of all fungi as they appeared, was practised with the mud extract agar plates, so that competition between species on the plates was greatly reduced.

Consideration of the fungi in Group 1 of Table 1 shows that where they were present in considerable numbers the individual frequencies of isolation on the two media were often remarkably similar. A detailed statistical analysis of each pair of totals showed that in no instance was there any significant difference between the two frequencies. Such tests were not applied where the combined total on the two media was below 20. Further analysis of Group 1 shows that, using fungal species as replicates, there was, for each community, no significant difference between the total isolation of Group 1 fungi on cellulose and on mud extract agar.

In two instances, placed together in Group 2, the results diverged from the pattern found for the previous group. Isolations of *Cephalosporium* spp. from the develop-

<i>Fusarium culmorum</i> (W. G. Smith) Sacc.	11	18	12	14	10	23

ing marsh at Gibraltar Point were significantly different ( $P < 0.05$ ) on cellulose agar and mud extract agar, though no significance was found between comparative isolations in the mature marsh or at Parkgate. The figures from which this analysis was calculated were obtained from the primary data which were in the form of monthly totals based on equal numbers of Petri dishes of each medium. *Fusarium culmorum*, while being isolated with similar frequencies on the two media from the Gibraltar Point communities, showed some differences between the media at Parkgate ( $P \sim 0.1$ ).

These data suggest that where the abundant cellulose-decomposing species are concerned they may be isolated with similar frequency on mud extract agar and on cellulose agar. The two exceptions show a majority of isolations from mud extract agar, which suggests that there were components of these taxa which were unable to decompose the cellulose particles and were therefore not recorded from the cellulose agar plates. This is of interest as it agrees with the situation as observed during the work. *Cephalosporium* is a very difficult genus to treat in a strict taxonomic fashion on the accepted morphological criteria. It would seem probable that several species were involved in the totals given, especially those for the plates prepared using mud extract agar. *Fusarium culmorum* is also a taxon which is subject to some discussion, and it may be that the isolates assigned to this species on mud extract agar were not all valid *F. culmorum*, or that this species has a wider range of variation in biochemical potential than in morphology.

The detailed data include only those fungi which were relatively abundant, but an examination of the full lists and totals obtained in the study shows that few species were isolated on the cellulose plates, even in low numbers, which were not also found on the mud extract agar soil plates. It may be suggested that the use of cellulose agar allows no marked additional spectrum of cellulose-decomposing fungi to be isolated. This would be in accordance with the accepted view that, although fungi may have a potential for decomposing complex substances such as cellulose, they also grow well on less complex energy sources, as provided by the non-selective media. Pugh *et al.*<sup>6</sup> came to a similar conclusion regarding the ubiquitous cellulose-decomposing fungi present in all the sites they examined, though they did not consider the remainder of the fungi, isolated from a more limited number of sites, to be regularly isolated on non-selective media. This is at variance with the data presented here, and in this context it must be stressed that these present results were obtained by using the complete Warcup technique<sup>5</sup>. Although this is very laborious, it does considerably increase the number of isolates and of species which are obtained.

There are, however, some very considerable practical advantages to be gained by the use of cellulose agar for certain types of soil mycological investigations. As was suggested by the initiators of the technique<sup>6</sup>, it allows a

rapid assessment of the population of cellulose decomposing species to be made and, as many sporulate more readily and more copiously on this medium, their identification is made more certain. It does not fully inhibit the growth of mucoraceous fungi but their growth is usually sparse, so that they do not over-run the slower growing species as much as they do on non-selective media. Cellulose agar is at present being used to investigate the distribution of certain cellulose-decomposing species in a number of soils where no information is required concerning other fungi present.

We thank Dr. D. M. Loeel for her advice.

## PSYCHOLOGY

### Correlation of Behaviour with Changes in Amplitude of Cortical Potentials evoked during Habituation by Auditory Stimuli

INCREASING attention has been directed to changes in the parameters of both evoked and spontaneous electrocortical activity in attempts to determine the electrophysiological correlates of behavioural awareness or attention, or the significance of sensory stimuli. In animal studies, habituation procedures have been used extensively and emphasis has been placed on the alterations which occur in the primary component of the sensory-evoked response. For example, it has been reported<sup>1,2</sup> that the iterative presentation of a brief acoustic stimulus induced a decrease in the amplitude of the primary response evoked in the specific auditory cortex. The behavioural criteria for habituation in these studies were not defined. Moreover, the sensory stimulus was presented over long periods of time and one would assume that any significance or meaning attached to it by the animal would have been lost long before a change occurred in the primary cortical response.

In order to study this question more fully, experiments have been carried out using five cat preparations with chronically implanted cortical recording electrodes. During the experiments the animals were housed in a sound-proofed cubicle and observations of behaviour were made by means of a closed-circuit television system. the camera

of which was placed in the roof of the cubicle. Tonal pips of 30 msec duration were used so that the frequency of the acoustic signal could be varied over a wide range. Frequencies between 800 and 10,000 c/s were employed and the tonal pips were presented from a loudspeaker also situated in the roof of the cubicle. The intensity of the stimulus at these different frequencies was equated for loudness to the cat<sup>3</sup>, being approximately 50 dB above the threshold for human hearing at 1,000 c/s. The acoustic signals were presented at intervals between 1 and 2 min.

Fig. 1A illustrates that within 30 presentations of a tonal pip of 3,000 c/s to an alert preparation, the secondary, surface-positive component of the potential evoked over the primary auditory cortex had decreased in amplitude by 50 per cent, while the primary, positive/negative complex still showed no significant change. This effect was specific for the 3,000-c/s stimulus, since potentials evoked by test stimuli of 10,000 c/s, presented before and after habituation to the 3,000 c/s tonal pip, still showed no significant change in either the primary or secondary components of the cortical response (Fig. 1B). Further repeated presentation of the 3,000-c/s stimulus was necessary before attenuation of the primary wave occurred.

It was difficult to correlate any precise behavioural observations with the attenuation of either the primary or secondary wave using stimuli of such short duration. This disadvantage was offset by increasing the duration of the tonal pip, a procedure which did not appear to produce any significant change in the latency, form or duration of the evoked responses. For example, the response evoked by a 30-msec tonal pip (Fig. 1A) was practically identical with the 'on' response initiated by a tonal stimulus of equal intensity and frequency, but lasting for five seconds (Fig. 2A). The only apparent difference between the two stimuli was in the intensity of the behavioural response which they evoked. The tonal pip produced little behavioural change other than an occasional ear movement, whereas the tone lasting 5 sec induced widespread cortical desynchronization and complete behavioural arousal. By using the latter criteria the behaviour of the animal could be correlated with the form of the evoked potential and the process of habituation followed more easily, for, as Sharpless and Jasper<sup>4</sup> have

Fig. 1. A, Superimposed monopolar recordings of cortical potentials evoked in the primary auditory cortex by a tonal pip (3,000 c/s) before and after 30 presentations of the stimulus to the alert animal. B, Similar cortical potentials evoked by a test stimulus of 10,000 c/s before and after habituation to the 3,000-c/s stimulus. Polarity - positive deflection upwards

Fig. 2. A, 'On' responses evoked in the primary auditory cortex. Potentials initiated by a 5-sec, 3,000-c/s tonal stimulus before and after habituation to the behavioural arousal response. B, Similar potentials initiated by a test stimulus of 600 c/s, which still produced arousal before and after habituation to the 3,000-c/s stimulus. Polarity - positive deflection upwards

pointed out, the repeated presentation of a tonal stimulus results in the progressive reduction and final obliteration of the period of electrocortical desynchronization, accompanied by abolition of the behavioural arousal response.

Repeated presentation of a 5-sec tonal stimulus of 3,000 c/s at approximately 2-min intervals produced habituation of the arousal response, usually within 20 to 30 trials, and also the progressive reduction in the amplitude of the secondary component of the evoked 'on' response in the auditory cortex. Comparison of the 'on' potential to tones inducing behavioural arousal at the beginning of the experiment with potentials evoked by the same tone after habituation demonstrates this latter point, and shows that the amplitude of the secondary, surface-positive component of the auditory-evoked potential follows closely the behaviour of the animal (Fig. 2A). Indeed, in the case of Fig. 2 the amplitude of the primary wave exhibited little change during the initial stage of the experiment. It was only following further presentation of the 3,000-c/s stimulus and after abolition of the behavioural response that changes became apparent in the amplitude of the primary component. Moreover, the change in the secondary wave was specific for the potentials evoked by the 3,000-c/s tone. Test stimuli at a frequency of 600 c/s, which induced arousal before and after habituation to the 3,000-c/s stimulus, still induced cortical potentials without any significant attenuation in the amplitude of either the primary or secondary waves (Fig. 2B).

These results appear to substantiate the view that it is the amplitude of the secondary, surface-positive component of the responses evoked in the primary auditory areas, rather than that of the primary waves, which is more closely related to the level of significance of the stimulus, at least in terms of its arousal or attentive value.

## FORTHCOMING EVENTS

Wednesday, July 28

**SOCIETY FOR ANALYTICAL CHEMISTRY, SPECIAL TECHNIQUES GROUP** (Joint meeting with the Polarographic Society, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Mr. K. G. Powell and Dr. G. F. Reynolds, "The Application of the 'Load-Line' Method to the Interpretation of the Effect of Resistance in Electrochemical Systems"; Mr. J. W. Howden: "Some Considerations in the Construction of a Cathode-Ray Polarograph".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

**POST-DOCTORAL FELLOW IN THE DEPARTMENT OF MATHEMATICS** to work on the application of quantum mechanics to conjugated molecules—The Registrar, The University, Nottingham (July 28).

**ASSISTANT LECTURER** (with a good honours degree (preferably also a higher degree), experience in research and/or industry, and preferably some teaching experience) in the DEPARTMENT OF APPLIED PHYSICS—The Secretary, Welsh College of Advanced Technology, Cathays Park, Cardiff, quoting Ref. No. DU878 (July 31).

**LECTURER OR ASSISTANT LECTURER** (preferably with interests in a branch of pure mathematics) in MATHEMATICS—The Registrar, University of East Anglia, Norwich Hall, Norwich, NOR 88Q (July 31).

**LECTURERS AND ASSISTANTS IN ZOOLOGY**—The Secretary of University Court, The University, Glasgow (July 31).

**RESEARCH ASSISTANT** in the DEPARTMENT OF GEOGRAPHY to work for one year on biogeographical aspects of the machair habitat in the Outer Hebrides—The Secretary of University Court, The University, Glasgow (July 31).

**RESEARCH ASSISTANT** (preferably with a higher degree and research experience in biochemical techniques) in the DEPARTMENT OF BOTANY, for a study, in association with Dr. G. G. Fritsch, of the effects of high pressures of oxygen on the enzyme systems of fungi and bacteria—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (July 31).

**SENIOR LECTURER (CLINICAL)** (with a higher qualification in surgery) in the DEPARTMENT OF SURGICAL NEUROLOGY—The Secretary, The University, Edinburgh (July 31).

**ASSISTANT LECTURER IN BOTANY**—The Secretary, Birkbeck College (University of London), Malet Street, London, W.1 (August 2).

**EXPERIMENTAL OFFICER** (with a degree or at least a Higher National Certificate in chemistry) in the DEPARTMENT OF CHEMISTRY to record infra-red and ultra-violet spectra required for research purposes and to organize the maintenance of spectrometers—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (August 3).

**ASSISTANT RESEARCH OFFICER OR RESEARCH OFFICER** (with training and experience in the use of a wide range of photogrammetric equipment) in PHOTOGRAMMETRY—The Registrar, University College of Wales, Aberystwyth (August 5).

**LECTURER** in the DEPARTMENT OF ELECTRICAL ENGINEERING—The Secretary, University College, Gower Street, London, W.1 (August 6).

**LECTURER OR SENIOR LECTURER** (with qualifications and research interests, preferably in some branch of mathematical statistics) in the DEPARTMENT OF PURE MATHEMATICS AND MATHEMATICAL STATISTICS—The Registrar, University College of South Wales and Monmouthshire, Cardiff (August 6).

**ASSISTANT LECTURER (veterinary graduate)** in ANIMAL HUSBANDRY—The Registrar, University of Bristol, Senate House, Bristol, 2 (August 7).

**PROFESSOR** (with teaching and research interests in the broad field of the sociology of industrial society, and an interest in the education of students of technology and science) of SOCIOLOGY—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting Ref. OST 65/62 (August 9).

**LECTURER (2)** in PSYCHOLOGY—The Secretary, The Queen's University, Belfast, Northern Ireland (August 10).

**TUTOR** in the DEPARTMENT OF GEOLOGY—The Registrar, University College of Wales, Aberystwyth (August 10).

**LECTURER** (with an appropriate degree of a recognized university, and preferably experience in the food preservation industry) in FOOD TECHNOLOGY at Hawkesbury Agricultural College, Richmond, New South Wales (N.S.W. Department of Agriculture)—New South Wales Government Offices, 66 Strand, London, W.1 (August 12).

**CHAIR OF ENTOMOLOGY** at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, August 13).

**RESEARCH ASSISTANT** in the DEPARTMENT OF PSYCHOLOGY (candidates who have recently graduated will be considered)—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (August 13).

**CHAIR OF CONTROL ENGINEERING**—The Deputy Secretary, The University, Southampton (August 14).

**LECTURER IN AGRICULTURAL ZOOLOGY**—The Secretary, The University, Aberdeen (August 14).

**LECTURER** (with a special interest in radio chemistry) in the DEPARTMENT OF CHEMISTRY—The Secretary, The University, Aberdeen (August 14).

**SENIOR LECTURER, LECTURER, SENIOR TUTOR** and a TUTOR in the DEPARTMENT OF MATHEMATICS, University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 14).

**RESEARCH ASSOCIATES** and **POST-DOCTORAL FELLOWS** in the SCHOOL OF ENGINEERING SCIENCE, for research posts in the fields of noise and vibration, metal fatigue, applied super-conductivity, automatic control or electro-chemical machining—The Registrar, University of Warwick, Coventry, Warwickshire (August 16).

**SENIOR LECTURER IN CHEMICAL PATHOLOGY** in the DEPARTMENT OF PATHOLOGY, University of Lagos Medical School—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.1 (August 18).

**CHAIR OF CHEMISTRY** in the DEPARTMENT OF PURE AND APPLIED CHEMISTRY—The Registrar, University of Strathclyde, George Street, Glasgow, G.1 (August 20).

**SENIOR RESEARCH ASSOCIATE** (with a Ph.D. or equivalent research experience in any relevant discipline such as physics, chemical engineering or metallurgy) in the SCHOOL OF MATHEMATICS AND PHYSICS, to work on the properties of liquid metals at high temperature and pressures in collaboration with Prof. N. W. Cowell—The Dean, School of Mathematics and Physics, University of East Anglia, Wilberforce Road, Norwich 77H (August 20).

**LECTURER** (with postgraduate qualifications in psychological medicine) in PSYCHOLOGICAL MEDICINE at the University of Adelaide, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, August 21).

**RESEARCH ASSISTANT** (graduate) in the DEPARTMENT OF GEOLOGY AND MINERALOGY for X-ray work on minerals—The Reader in Mineralogy, Department of Geology and Mineralogy, University of Oxford, Parks Road, Oxford (August 21).

**LECTURER OR ASSISTANT LECTURER IN PHYSIOLOGY**—The Registrar, The University, Sheffield (August 23).

**LECTURER OR ASSISTANT LECTURER** (with interests in either high temperature inorganic chemistry or chemistry of non-transition elements) in INORGANIC CHEMISTRY—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol 7, quoting Ref. OST 65/72 (August 31).

**LECTURER** (preferably with a knowledge of plasma physics) in PHYSICS at the University of Natal, Durban—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 31).

**SENIOR LECTURERS OR LECTURERS** in the SCHOOL OF PHYSICS, University of Melbourne, to carry out teaching and research in theoretical, nuclear or solid state physics, or in electron and X-ray diffraction—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 31).

**ASSISTANT LECTURER IN BOTANY**—The Secretary, The Queen's University, Belfast, Northern Ireland (September 1).

**LECTURER** (with a good honours degree in engineering or physics and preferably research interests in the field of experimental reactor physics) in the NUCLEAR POWER GROUP of the MECHANICAL ENGINEERING DEPARTMENT—Dr. P. J. Grant, Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7 (September 1).

**LECTURER/SENIOR LECTURER IN MATHEMATICAL STATISTICS** at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 3).

**SENIOR LECTURER IN PHYSIOLOGY**; and a **LECTURER OR ASSISTANT LECTURER** in PHYSIOLOGY (suitably qualified persons interested in any of the fields of animal physiology)—The Secretary, The Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (September 14).

**VISITING PROFESSOR** (preferably with a research background in geo morphology and/or climatology) in GEOGRAPHY for one year at Aarhus University—Aarhus Universitet, Aarhus C, Denmark (November 1).

**ASSISTANT LECTURER** in the DEPARTMENT OF FOOD SCIENCE—The Registrar, University of Strathclyde, George Street, Glasgow, G.1.

**ASSISTANT LECTURER OR DEMONSTRATOR** in the DEPARTMENT OF PATHOLOGY—Prof. W. A. J. Crane, The University, Sheffield, 10.

**ASSISTANTS (2)** (graduates in geography or botany) in the DEPARTMENT OF GEOGRAPHY, to help with vegetation mapping and associated research projects—The Registrar, University College of Wales, Aberystwyth.

**HISTOCHMIST**, Basic Grade (preferably with an honours degree in chemistry or biochemistry or equivalent qualification) for the Sunderland Hospital Group Laboratory Service—The Hospital Secretary, Royal Infirmary, Sunderland.

**CHAIR IN COMMUNICATIONS THEORY**; and **CHAIR IN ACCOUNTING**—Dr. G. L. d'Ombra, Chairman, Electrical Engineering Department, McGill University, Montreal, Canada.

**FISHERIES OFFICER** (national of the United Kingdom or the Republic of Ireland, with a good science degree and experience in fisheries management, including marketing and processing) in Malawi, to collect statistics and develop and demonstrate to local fishermen improved methods of fishing appropriate to local conditions—The Appointments Officer, Room 301, Ministry of Overseas Development, Strand House, Stag Place, London, S.W.1, quoting Ref. RO 289/134/01.

**GRADUATE** (with an honours degree in agriculture or other appropriate science) to work on the bull register of the Breeding Research Division—The Personnel Officer, Milk Marketing Board, Thames Ditton, Surrey.

**JUNIOR RESEARCH ASSOCIATE** (preferably with a first or upper second-class honours degree in physics, chemistry or metallurgy) in the SCHOOL OF PHYSICS, to work on research projects in the fields of solid state physics and the physics of materials, under the direction of the Professor of Physics, and to register for a higher degree—The Registrar, University of Warwick, Coventry, Warwickshire.

**LECTURER (2)** in OPERATIONAL RESEARCH OR INDUSTRIAL ENGINEERING; **ASSISTANT LECTURERS** in OPERATIONAL RESEARCH; and an **ASSISTANT LECTURER** in PRODUCTION TECHNOLOGY—Prof. B. Hiron, Imperial College of Science and Technology, 14 Prince's Gardens, London, S.W.7.

**PHYSICAL CHEMISTS** to work in the field of thermodynamics, thermodynamics, high temperature chemistry, and on the deposition of metals by vapour phase reaction—The Director of Research, Fulmer Research Institute, Stoken Park, Bucks.

**RESEARCH ASSISTANT** (graduate or expecting to graduate this summer) in PLANT PHYSIOLOGY under the supervision of Prof. M. B. Wilkins, Professor of Biology—The Dean, School of Biological Sciences, University of East Anglia, Wilberforce Road, Norwich, NOR 77H.

**RESEARCH ASSISTANT** (with a Ph.D. or B.Sc. or equivalent in chemistry, mathematics or physics, and interested in the application of computer techniques to molecular theory) in THEORETICAL CHEMISTRY—The Secretary, Royal Holloway College (University of London), Eghfield Green, Surrey.

**RESEARCH ASSISTANT** (graduate in agriculture or agricultural botany) in CROP HUSBANDRY for work on the potato crop—The Secretary, The School of Agriculture, West Mains Road, Edinburgh, Scotland.

**RESEARCH FELLOW** (preferably graduate mathematician, physicist, aerodynamicist or physical chemist) in the DEPARTMENT OF AERODYNAMICS to carry out theoretical and/or experimental work on topics in the field of real-gas dynamics—The Registrar, The College of Aeronautics, Cranfield, Bedford.

**RESEARCH FELLOW** (with a higher degree or extensive postgraduate experience, and an interest in one of the following fields: particle mechanics, process dynamics, mass transfer or petroleum technology) in the DEPARTMENT OF CHEMICAL ENGINEERING—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 30/G.

**SENIOR LECTURER OR LECTURER** (preferably with a special interest in the geography of Africa) in GEOGRAPHY at the University College, Dar es Salaam (University of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.1.

**SENIOR OR CHIEF TECHNICIAN** in the SCHOOL OF MATHEMATICAL AND PHYSICAL SCIENCES, to work under the general guidance of the Professor of Experimental Physics on atomic beam research projects concerned with gas scattering, optical and electronic excitation and radiofrequency resonance—The Laboratory Superintendent, Physics Laboratory, University of Sussex, Fulmer, Brighton, Sussex.

**SENIOR PHARMACEUT** (full- or part-time)—The Physician Superintendent, Oakwood Hospital, Maidstone, Kent.  
**SENIOR RESEARCH ASSOCIATE IN THE SCHOOL OF CHEMICAL SCIENCES** for work in the preparation and spectroscopic study of dicyclic aromatic molecules or coordination compounds—Prof. S. F. Mason, School of Chemical Sciences, University of East Anglia, Wilberforce Road, Norwich, NOR 77H.  
**SILVICULTURIST** (national of the United Kingdom or the Republic of Ireland, with a good degree in forestry with a minimum of one year's relevant postgraduate training or experience) in Sabah, to supervise the silvicultural and geological research of the Forest Department, to study methods of natural regeneration of Dipterocarp forests, to establish species trial plots and afforestation techniques, and to analyse and record data from regeneration surveys—The Appointments Officer, Room 301, Ministry of Overseas Development, Bland House, Stag Place, London, S.W.1, quoting Ref. R0234/150/02.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

**Ministry of Technology. Forest Products Research 1964: Report of the Forest Products Research Laboratory Steering Committee with the Report of the Director of Forest Products Research.** Pp. vi+54+12 plates. (London: H.M. Stationery Office, 1965.) 6s. 6d. net. [16]

## HIGHER EDUCATION IN BRITAIN

THREE of the papers presented at a discussion on universities and social fabric, arranged jointly by Section J (Psychology) and Section N (Sociology) at the meeting of the British Association for the Advancement of Science at Southampton in September 1964, have recently been published (edited by Prof. J. Drever) in *The Advancement of Science* (22, 29; May 1965). In the interval they have become even more pertinent to developments in higher education and to some current discussions about university places, and particular shortages, such as those of engineers and physicists. This was apparent at the Home Universities Conference in December 1964, for example, although ostensibly that Conference was concerned with university teaching methods and with the finance of universities.

In the first of these three papers, Prof. J. Drever himself discusses need, choice and supply in higher education. His experience in the United States as well as in Britain leads him to suggest that more ought to be known about the academic motives of our young people before we can plan ahead with confidence. It is not just that the mounting scale of investment in higher education leads to questions concerning the rate of failure or to the relation between supply and demand in particular occupations being viewed with greater concern. There is, Prof. Drever suggests, a possibility that the demand for places in higher education may be self-limiting in some way and that this limitation may not be an adaptive one. The delicate balance between ambition and impatience, between conformity and impatience, may easily be upset, with consequences that may not be predictable.

Again, as regards choice, he points out that the Robbins Report has scarcely faced the real issues. It is unrealistic to suppose that the needs of the community are invariably met by the decisions of its adolescent members or to assume that the changing demands of research and industry are necessarily reflected in an educational system which tries to keep central planning and direction to a minimum. There are indeed no easy answers to such questions, and the whole tenor of the replies recently given in Parliament to questions about the work of the Committee on Manpower Resources for Science and Technology suggests that a much more realistic view is now being taken both by the Minister of Technology and the Secretary of State for Education and Science. Britain cannot, Prof. Drever observes, afford the luxury of complete freedom of the American way, but it is equally questionable whether some measure to eliminate or minimize the element of chance which often determines the choice of curriculum necessarily means a serious infringement of liberty.

So far as engineering and technology are concerned, attention is already being directed to the correction of some bias which acts against the choice of these careers. Further action, however, may well be expected when the examination by the Tavistock Institute of Human Relations on factors affecting the status of engineers in society is completed by mid-September. Even so, as Prof. Drever emphasizes, there will remain the question of standards, and here also we know too little to take them for granted. In the face of the present uncharted drift of academic standards, we need objective standardized tests at various crucial stages in the educational process. These would have to be kept flexible and

sensitive to new developments, and this Prof. Drever maintains is possible.

The second paper, by Dr. W. Taylor, discusses university culture and social change, and once again directs attention to the lack of knowledge about important aspects of university life. Few would dissent from the view that the work of universities is central to the processes of social and technological change in an industrial society, but there is little hard evidence of the effect of residence in hall on the student on which to base proposals for expansion of such institutes. Obviously to judge soundly the extent of such influence on students, something should be known of the values and attitudes of student sub-cultures. Dr. Taylor urges that we need many more systematic analytical investigations of the interaction of the various groups that make up the university, the social processes that are involved in providing and receiving a higher education and of the way in which universities relate to other institutions within society and respond to the demands made on them. He calls for clarification of some of the observations of the Robbins Committee, asking how university life is to compensate for differences in home background, and exactly what type of social habitat the Committee had in mind for a university.

It is salutary to be reminded that there is little firm evidence to support the wide claims that are made for the effects of the residential life, and Dr. Taylor recognizes that it is much easier to be critical than constructive about the socializing function of the university: reconciliation of ideological diversity, individual liberty and a sufficient measure of consensus to make social life possible cannot be easy. Even more to the point, he insists that it is above all with the intellectual hazards of university life that we have to be concerned. It is these that are most threatened and also most commonly overlooked, and it is also the values and types of judgment represented by scholarship and the scientific temper which, as Dr. Taylor justly remarks, must be fought for anew with each group of students entering the university. Halls of residence, college units and moral tutors are no substitute for curricular reform, well-equipped libraries and laboratories and improved teaching and examining.

Even more specifically than Prof. Drever, Dr. Taylor puts first things first, nor does Prof. A. Rodger fall behind him in the third of these papers on capacity and inelination for university courses. Further, he underwrites Prof. Drever's insistence on the importance of inelination, which does not always run with capacity. Refusal to recognize this may involve both social waste and individual misery. The warning of Lilje's *The Abuse of Learning* has implications far outside Germany. Moreover, excessive preoccupation with capacity can lead to too much stress being placed on attainment and too little on intelligence.

That is a criticism that has been authoritatively voiced since the Southampton meeting of the British Association, but Prof. Rodger goes on to add that there is a further danger that we may fail to appreciate properly some of the pointers provided by recent work on the relation between capacity and social class. Here he is thinking of social class as a factor facilitating or hindering the inelination to study, and more especially of the task of assessing fairly the candidate whose capacity and inelination for university work have, in a sense, become

atrophied through unfavourable home circumstances. Since we already know that both capacity and inclination are influenced by various environmental factors, this may well mean in practice that available information on the relations between attainment intelligence and social class is likely to lead to underestimates of our reserves.

It could also be asked whether sufficient attention has yet been given in the universities, either in planning courses or curricula, or in the provision of facilities and methods of teaching, to the effect of the influence of an increasing number of students from homes with no tradition of learning or facilities for study. Both considerations become the more important when concern with university finance raises the question of benefit to the community from the investment involved. Prof. Rodger raises a further related point. There is also the danger that addiction to specialization may make it impossible for us to investigate systematically the limits of educational and occupational versatility. Quite rightly, he urges that in these days of rapid and extensive technological change, and consequent occupational change, versatility of both capacity and inclination deserves far more study than it receives. For all the talk about general or broadly based education at any level, this question of versatility or adaptability is scarcely mentioned. Yet if rigidity is to be checked, and if automation, for example, is not to lead to unemployability as well as unemployment, this aspect is of paramount importance.

Prof. Rodgers is inclined to put some considerable measure of responsibility for the present situation of specialization on academic circles, though he recognizes that the University Grants Committee has for some years been fostering the notion of the joint honours degree. If these became common, he thinks that our present ignorance would be reduced a little and at the same time our students could be given a chance to find out methodically what they are best at and enjoy most. Systematic studies of planned procrastination in the choice of school and university courses, he suggests, are much more likely to advance our knowledge of capacities and inclination than any amount of early specialization.

Finally, he refers to the danger that concern for the younger age-groups may lead us to neglect the special problems of the mature university student. For various reasons, these are increasing in numbers and many students for higher degrees are men and women anxious to make progress in their chosen line. Often these will, of necessity, seek part-time courses; some may desire to change their discipline; and Prof. Rodgers reminds us that sometimes the older, experienced part-time students are better fitted than others to pursue particular researches. Studies of reserves of capacity and inclination for university courses should accordingly take account of the potential among the mature, whose needs are not invariably met by extra-mural courses and are frustrated by the customary Government parsimony in that field.

These suggestions are not likely to be particularly welcomed by Ministers and their administrators, especially when they involve or imply freedom for rigorous experiment. Prof. Rodgers admits that projects for research in social science must be technically sound, administratively convenient and politically defensible, but the last two of these three criteria may tend to exclude experiment, and he adds that we must be prepared to use survey methods extensively. Nevertheless, unless due attention is paid to the points made in these three papers, Britain is

unlikely to avoid serious errors in the expansion of higher education and a waste of talent and of public money that can ill be afforded.

The discussion at the Home Universities Conference\* on the report of the Hale Committee on University Teaching Methods, which Sir Edward Hale himself opened, brings out the importance of these views. Sir Edward was content to emphasize his own experience of the value of the tutorial in teaching him how to read up a subject, to think clearly for himself, and to use language to communicate his thoughts. He added that it was necessary for every student to stretch his ability to the utmost: the purpose of the tutorial was not to make things easy for him. If university expansion necessitated reduction in any form of teaching, the last thing to go should be teaching by discussion with students of their written work.

Prof. R. J. Blin-Stoyle also stressed the vital importance of effective contact between staff and students, including a continuous and firm relation between a student and at least one member of the staff, in which the student became increasingly independent. He added that, at least in science, effective and stimulating teaching stemmed from a background of research and enquiry, and the teaching system must leave time for the university staff to put in a substantial research effort. Plans for university expansion which endanger this balance are unlikely to be effective. He also referred to the desirability of flexibility and transfer from one department to another, and his remarks fully substantiated much that Prof. Rodgers, Prof. Drever and Dr. Taylor had said at Southampton.

Throughout the discussion at the Conference these points were reiterated in different ways. Prof. E. Wright referred, for example, to the importance of the library in giving the student a sense of belonging to a community of scholars. Moreover, while Mr. H. J. Perkin referred to the desirability of excellence as a teacher being rewarded, and being seen to be properly rewarded, and while this was in support of what the Robbins Committee had said, it should not be at the expense of research. Prof. Wright again referred to the real danger of universities being regarded more and more as service institutions, professional training schools, or technological institutions. However, both Prof. A. G. N. Flew and Dr. F. G. Healey, in remarks that linked this discussion with the subsequent one on the financing of universities, referred to the importance of using university institutions more economically and using the teaching machine to do precisely those things that the teacher does not do, for taking all those service courses which are meant to equip the student to do another course better.

The discussion on the financing of universities started from the problem of striking a balance between the freedom of a university to develop its academic programme and the legitimate demand of Government for some control over the large sums of public money provided, at least to the extent of being satisfied that a reasonable return was forthcoming. Like the discussion at Southampton, however, it began by emphasizing the absence of reliable information on this latter aspect. As Mr. S. F. Burman, the Pro-Chancellor of the University of Birmingham, observed in opening the discussion, there is an

\* Report of the 1964 Home Universities Conference, University of London Senate House, 11th and 12th December, 1964. (The Report of the Committee on University Teaching Methods. The Financing of Universities.) Pp. 76. (London: The Association of Commonwealth Universities, 1965.) 5s.

almost complete lack of meaningful statistics on which valid judgements can be made as to the worthwhileness of any particular form of expenditure; the formulae by which we justify our capital expenditure are crude; and there is no efficiency audit on what we do.

First, Mr. Burman suggests, we should work out our actual costs for tuition per student, department by department, taking into account maintenance, capital and all the other factors involved, and thus avoiding the considerable distortions in the present method. The work already done on specific research grants could well be extended to grants for the research which arises naturally out of tuition or the individual purposes of the academic staff. Enquiry into the wider aspects of capital expenditure again might well reveal a correlation between teaching costs, research costs and capital costs. He also thought that it might be useful if Britain's provision of finance to universities were devised so as to provide each university with a positive incentive to the optimum utilization of that finance, with freedom to vary the cost/quality balance. Moreover, Mr. Burman said frankly that the mounting cost of university education forced consideration of the question of whether we were justified in accepting any student who presented himself or herself, with appropriate entrance qualifications, to be educated at the public expense in the discipline of his or her choice, irrespective of whether there was an ultimate demand for those with that particular type of training.

In pointing out that, if university education is regarded as training for a vocation, we must make some careful attempts to measure the demand, Mr. Burman was not merely endorsing Prof. Drever's argument. He was emphasizing the truth which it is so fashionable to ignore—that university education is not a right, but a privilege, and as such carries responsibilities. These responsibilities, it might be added, are commonly ignored by those who are most forward in urging that the universities are primarily places of vocational or professional training. The realism which marks this whole discussion has some implications that may well prove awkward for the Minister of Technology and the Secretary of State for Education and Science unless their declared outlook has changed. It is not merely that the discussion provides welcome and unmistakable evidence of a readiness on the part of the universities to look more closely into their financial control, efficiency, organization and methods of government. Dr. H. M. Taylor, Vice-Chancellor of the University of Keele, seized the opportunity to refer to the importance of a firm assurance of sufficient resources to enable general developments to be planned five years ahead without erosion by rising costs. There was sanity also on the question of students' fees, and Sir Edward Hale strongly supported Dr. Taylor's argument for raising these. This was, however, questioned by Dr. M. B. Sutherland and Prof. A. G. N. Flew, who preferred the introduction of a loan element in student finance, and were supported by Mr. A. W. Jones.

These details are of secondary importance, however, compared with the extent of the evidence that the universities themselves are prepared to think realistically on matters of finance, not only in terms of control of expenditure and their own internal administration but also in terms of teaching methods and the benefit to their students and to the community. Obviously this involves some fresh thought about the purpose of a university, for no sound judgment can be formed as to the return on

university expenditure unless we are clear in our minds as to what that purpose should be. Here it would seem that the universities are ahead of the Government; it is surely significant that both at Southampton and at the Home Universities Conference attention should be directed as emphatically to the gaps in our knowledge as to the effectiveness and appropriateness of many existing practices. Primarily, the need is for fact-finding rather than research, between which Lord Heyworth's Committee has since drawn a sound distinction. However, the necessary enquiries call for studies in the social field, and the recommendation of the Heyworth Committee for a considerable extension of social research is emphatically endorsed. It may not be too much to add that if the Government is really concerned to ensure the maximum public return from expenditure on higher education, it would be wise to ease the pressure on universities to increase the number of places. Certainly, this should be done while answers are being sought to questions such as were raised by Prof. Drever and other participants in the discussion at Southampton, as well as at the Home Universities Conference. If any choice has to be made, more finance should be provided for the social research required before that for further expansion of the universities.

## THE WORLD OF ARIEL

### The Golden Age of Wireless

By Asa Briggs. (The History of Broadcasting in the United Kingdom, Vol. 2.) Pp. xvi + 688 + 54 illustrations. (London: Oxford University Press, 1965.) 75s. net.

LIKE broadcasting itself, Prof. Asa Briggs has made a significant contribution to the history of our times. His first book in a projected four-volume history of broadcasting in the United Kingdom described the birth of wireless. This, the second, is concerned with the period from 1927, when the British Broadcasting Corporation ceased to be a private company and became a public corporation, up to the outbreak of war in 1939. The period has been chosen with care for it represents more than the passing of a limited experiment of interest mainly to the participating few. It stands for the establishment of a national service with implications and repercussions not only for British citizens but also, because of the way it was shaped, for humanity. The shaping, as Briggs makes crystal clear, was due to the leadership of a man who, above all, stood inflexibly for the dissemination of truth and the upraising of moral and cultural standards. Not for Reith to project a Government or cheap commercial interests. Thus, for all that, Briggs has continued his story for a period of one year after the departure of the B.B.C.'s first Director-General, this book is almost entirely an account of Reith's successful attempt to build a large-scale public corporation.

To obtain his information Briggs has had to dig deep and wide. Diaries, memos, newspapers, journals, conversation, Government and many other sources of information have been used and brought together with great scholarship and skill to produce a book which everywhere pays tribute to the genius of Reith even when recording his imperfections. It should be a source of delight and interest especially to those who lived through the period under review. Many nostalgic memories will be revived and half-forgotten incidents recalled. Older readers will, for example, remember Stuart Hibbard's memorable "The King's life is moving peacefully towards its close", John Hilton, Howard Marshall and John Snagge, the bulletins about the *Thetis* disaster in 1937, the first broadcast Promenade Concerts, football match recordings by George

Allison, Band Waggon, Saturday Night Music Hall, and the Sunday Night Services from St. Martin-in-the-Field's, Stephen King-Hall on Children's Hour, outstanding broadcasts to schools, and many, many others.

Although television was well established by 1939, its range was still limited to the London area and viewers were comparatively few. For those, this book will bring memories of studio plays and pantomimes, the Boat Race and the Coronation, Jasmine Bligh and Elizabeth Cowell and other well-known personalities. Among the half-forgotten facts which will occasion surprise is that, up to the outbreak of the Second World War, no broadcasting of any kind took place before the daily service at 10.15 a.m. and no regional variations were permitted before the start of Children's Hour.

The value of *The Golden Age of Wireless*, however, lies less in programme remembrances and more in the revelations behind them. The scientific and technological developments required for the transmission of radio waves over long distances are accurately portrayed and are only excelled by Briggs's fascinating account of how Baird's intrepid struggle to establish a successful means of televising ended in tragic failure. The political warfare with successive Governments about ultimate control of broadcasting, the cheese-paring attitude of Ministers and senior Civil Servants, and the ineptitude of a prominent Postmaster-General, help to explain at least some of the reasons which led to apparently slow progress in the development of regional broadcasting and programmes designed especially for overseas listeners. Students of management, too, will find much that is familiar in the way in which Reith built up a large organization on functional lines with constant adaptation to meet changing need, and where the span of control and the matching up of authority and responsibility were well conceived and executed.

The vastness of the book and the detail of its record, however, may account for its greatest imperfection. Many students of social history and sociology would wish to have read more of Briggs's views on the impact of wireless on public taste and opinion. Has the broadcasting of 'good' music led to a real improvement in standards? Among the more intelligent only? What of the effect of 'poor' music and variety on the less intelligent? Were the B.B.C. right to establish such a marked middle-class image? What effect has there been on politics, and on the practice of religion? Has individuality suffered and the creative spark been dimmed? Should not much more have been done to use the radio as a deliberate means of adult education? Has the B.B.C. played its part in the evolution of an industrial society the continuance of which depends on the success of its manufacturing industries? Could knowledge of developments in science and technology have been more widespread? What Briggs has successfully done is to provide the necessary information which others could use to dig even deeper in unearthing the answers to some of the questions posed. What he has done even better is to pay public tribute to the man who so built the B.B.C. that its reputation for integrity stands unrivalled in broadcasting systems throughout the world.

T. H. HAWKINS

## TECHNOLOGY AND APPLICATION OF RADIOACTIVITY

Die Technischen Anwendungen der Radioaktivität  
Band 1. Von Dr. Engelbert Broda und Dr. Thomas Schönfeld. 3. verbesserte und stark erweiterte Auflage. Pp. 372. (Leipzig: Veb Deutscher Verlag für Grundstoffindustrie, 1962.) 32.50 D.M.

**D**RS. Broda and Schönfeld's well-known book on the technological applications of radioactivity has now reached its third edition. There has been so much

progress in the subject that it has become necessary to redistribute the material into two volumes, the first of which has now been published. The second volume is promised for the near future.

The basic plan of the previous editions has remained unaltered; but the chapters in the second edition on "Absorption and Scatter of Radioactive Radiation in the Technique of Measurements" and "The Technological Applications of the Effects of Radioactive Radiation on Matter" will appear in Volume 2. The chapter on protection against radiation remains at the end of Volume 1. Examples of stable isotopes used as markers, mainly in cases where radioactive isotopes of elements are too short-lived, have been given in this volume, though without any description of working methods and measurements, since these are not the main topic.

The initial chapter contains a concise summary of the basic facts of radioactivity necessary for a full understanding of the technological applications, followed by a survey of methods of measurement. There is also a review of the various applications of radioactivity to the wide field of chemical analysis and a discussion of the methods of analysis by activation, by indicators, by isotope dilution, etc. The remainder of this volume deals with more specific technological applications in the mining and oil industries, in general and specific problems of the chemical industry, and finally in agriculture and forestry. The treatment of all these items is not exhaustive with regard to detail; the reader who requires detail can look it up in the bibliography attached to each separate section.

The book is very clear and readable, and the text benefits from the avoidance of detail and from the occasional judicious use of examples. For anyone who requires information about the existing technological applications of radioactivity this book will prove a suitable and reliable source.

W. M. DALE

## III-V COMPOUND SEMICONDUCTORS

### Physics of III-V Compounds

(Wiley Series on the Science and Technology of Materials.)  
By Prof. O. Madelung translated by Dr. D. Meyerhofer.  
Pp. xiv + 409. (London, New York and Sydney: John Wiley and Sons, Inc., 1964.) 98s.

**T**HE discovery by Welker of the III-V compound semiconductors had the effect of enormously widening the field of semiconductor research not only by the inclusion of the III-V compounds themselves but also by suggesting that there might exist other classes of binary, ternary and even more complex semiconducting systems. The resulting comparative investigations of different semiconductors have been extremely valuable in elucidating the underlying principles governing their behaviour. This applies particularly to the problem of band structure, as is made clear in the second and final chapters of Prof. Madelung's book, *Physics of III-V Compounds*.

One question that must be answered before discussing the book in detail is whether its appearance is timely. There is a contradiction to overcome here since if one waits for a topic to become quiescent before writing a book on it, one may find that readers are no longer interested. The author, I think, justifies himself in the preface where he correctly states that the main features of the phenomena observed in III-V compounds were correctly understood by about 1962 and that present-day research is largely directed towards the solving of technological problems. To this one might add the investigation of phenomena, in themselves interesting, for which some III-V compound provides a particularly suitable medium. It certainly seems unlikely that the picture of the III-V compounds presented in this book will undergo any considerable modification in the near future, though a comparison with Hilsenrath's slightly later review at the

semiconductor conference in Paris does show some quantitative changes.

After an introductory chapter in which the history and crystallography of the III-V compounds were discussed, the author discusses band theory as it applies to these substances. This is supplemented by some brief remarks concerning the chemical binding which emphasize the persistent failure of the 'band' and 'bond' pictures to coalesce. The review given in this chapter is of considerable value though in the case of the k.p. theory it would have been better if either less detail or more explanation had been given.

The chapter on optical properties is probably the best in the book. It consists of a review of optical methods of studying band structure, with illustrations drawn from the III-V compounds, and is to be recommended to anyone interested in understanding how these techniques are used. The degree of sophistication and subtlety in experimentation and interpretation is very well brought out; by comparison the picture derived from the transport properties lacks precision. It is only where a detailed numerical calculation has been carried out that one feels confident in the analysis of the experimental data. This situation probably explains why the chapter on transport properties has much more of the character of a compilation than that which precedes it. The same is almost inevitably true of that dealing with mixed crystals and ternary compounds.

The subject of impurities and defects must have been difficult to deal with, since it is in this area that many of the unsolved problems crop up. Consequently there are probably more controversial assertions here than elsewhere, though it seems to me that fair treatment has been given to conflicting points of view.

The survey of p-n junction phenomena is probably the place at which the timing of the book was rather unfortunate owing to the discovery of the diode laser. Only the briefest account of this subject is given, and it will certainly bulk larger in any subsequent edition Prof. Madelung may bring out.

There is a very complete bibliography up to the beginning of 1964 and the division into subject and substance indexes is useful. The translation only rarely reveals that the book was originally written in German and is only positively infelicitous on the dust jacket. This book should prove of great value to all those interested in the physics of III-V semiconductors.

J. E. PARROTT

## ASSESSMENT OF OPTICAL SYSTEMS

Fourier Methods in Optical Image Evaluation

By Dr. E. H. Linfoot. (The Focal Library.) Pp. 90. (London and New York: The Focal Press, 1964.) 50s.

THE assessment of optical systems has, traditionally, been predominantly by spot diagrams derived from ray-traces. That of photographic emulsions has been in terms of subjective 'graininess' and 'limiting resolution'. These means are no longer adequate for the assessment of modern high-performance optical systems.

Even if the spot-diagram fully represented the optical performance, its interpretation would remain ambiguous; it is not evident whether a concentrated core surrounded by a relatively weak but extended halo is better or worse than a comparatively uniform spot-distribution of moderate size. In fact, of course, the spot-diagram distribution does not represent the image structure even qualitatively when the aberration-spreads and diffraction-spreads become comparable, since the diffraction-spread corresponding to an aberrant zone (Babinet's principle) may then exceed the whole ray-theoretic image spread.

The fact that almost all images of interest are eventually presented to the human retina provides some justification for the subjective assessments traditionally

used in photography. It has become increasingly clear, however, that 'graininess' and 'limiting resolution' are not well defined either conceptually or operationally, and they do not obey any practicable calculus.

Finally, the assessments traditionally applied to optical systems and to photographic emulsions have been mutually isolated. There has been no means of combining spot-diagrams, diffraction-spreads, and photographic characteristics of noise and resolution into an overall assessment of a photographic optical system.

In recent years, these difficulties have been overcome by the application of the methods of communication theory, and their further development for optical applications. Because of the wave-nature of light, an optical image is effectively band-limited, and because of the particle-nature of light the image has a finite signal-to-noise ratio. It follows that the image has a finite information content. Roughly speaking, this means that it is capable in principle of distinguishing one out of a finite set of object intensity-distributions. Useful assessments can be formulated in terms more or less closely related to the extent to which a practical optical system approaches the theoretically possible discriminating-power corresponding to its size and the amount of available light.

The basic analytical tool for these assessments is the Fourier theory. The object- and image-distributions are analysed into their orthogonal sinusoidal components. These components are propagated through an optical system with (in a useful approximation) change only in amplitude and phase; this is a much simpler situation than that for point-components of the object distribution, which may change shape in a complicated manner. The performance of the whole system can be expressed completely (in this approximation) by specifying, as a function of frequency of the sinusoids, the change in signal-to-noise ratio and contrast between object and image distributions. The treatment is implicitly wave-theoretic, although ray-approximations can be derived in some circumstances; photographic effects are included. From these full descriptions it is possible to abstract figures of merit, each of which may be expected to be especially useful in particular circumstances; in particular, it is possible to specify the performance in relation to a prescribed object-set. It turns out that most of the intuitively satisfactory abstractions are closely related, so that it is seldom necessary to make a decision between them.

Dr. Linfoot has played a leading part in these developments, and his book provides a welcome exposition of the basic theory, and of some illustrative results, within the pages of a single compact volume. A careful balance has been maintained between the mathematical and physical content; the basic Fourier theory is collected in an appendix, and the whole treatment requires for its understanding no mathematical technique beyond elementary analysis. After a preliminary chapter exposing the problems and intentions, the processes occurring in optical and photographic imaging are treated by Fourier methods. This leads up to quality assessments of optical and photographic images, and numerical results are given illustrating the interaction between wave aberrations and photographic spread in some selected special cases. The general theory is equally applicable to receiving surfaces other than photographic, and in particular to photoelectric image devices.

The standard of production of the book is high. The paper and layout appear excellent, and the type-face untiring to read. The price works out at about sixpence-halfpenny per numbered page. Since this is more than the cost of duplication on the best present-day office copiers, it raises the question of what part printing ought to play in the dissemination of scientific knowledge to-day. This is not, of course, a reflexion on the merit of the book itself, which can be confidently recommended.

P. FELLGETT

## MAGNETIC RECORDING TECHNIQUES

Proceedings of the Conference on Signal Recording on Moving Magnetic Media

Berichte der Konferenz über die Signalspeicherung auf Bewegten Magnetischen Medien, Budapest, 15. 18. Oktober 1962. Pp. 470. (Budapest: Akadémiai Kiadó, Publishing House of the Hungarian Academy of Sciences, 1964.) 12 dollars.

THIS is a well-produced book of some 470 pages which gives the full text of all the papers that were read at a conference on "Signal Recording on Moving Magnetic Media" held in Budapest during October 15-18, 1962. There are 37 contributions, about two-thirds of them from East European countries, principally East Germany and Hungary. The remaining one-third of the contributions are from West Germany, Britain, the United States, Belgium and France.

It is stated that the conference was originally planned as a Hungarian rather than an international one and this, no doubt, has influenced to some extent the geographical distribution of the contributors as well as, in some cases, the presentation of the material submitted.

The papers are all published in their original languages, about two-thirds of them in German but with contributions also in English, French and Russian. As is to be expected with the record of a conference of this kind, the papers vary both in merit and in length, while the diversity of subject-matter is such that it is difficult to indicate the range covered by quoting a few general categories into which the papers may be divided. Indeed, the Editor, faced with this difficulty of presenting the papers under a series of headings, has wisely taken refuge in printing them in the alphabetical order of the authors' surnames. As some indication of range let it be said here that, taking six papers more or less at random from the index, the subjects dealt with include a 1½-in./sec magnetic recording system for stereophonic music, the magnetic recording of seismographic data, a proposed new double 8-mm magnetically striped film, the recording of single television pictures on magnetic disks, the measurement of fluctuations of speed in magnetic tape equipment and the application of information theory to recording systems.

Because of the width of the field covered, it is inevitable that there will be few private purchasers for this book who will have a close interest in all of the papers, the more so since four languages are used. Some private purchasers might therefore feel that the equivalent of 12 dollars is a high price to pay for the fraction of the book that they want.

The volume remains, nevertheless, an excellent permanent record for library use, but some caution is necessary if only because progress in this field is still active and what was an up-to-date account in 1962 may be less satisfactory in 1965. For example, there is an excellent paper by Gondeesen surveying the techniques of synchronizing magnetic tape sound recordings with picture film for television use. The survey is confined to practice in West Germany and, except for the frequency modulated track used in connexion with the Electronic-Cam system, the only type of tape synchronizing track described is that recorded transversely over the whole width of the tape. However, an arrangement using two narrow tracks down the centre of the tape and carrying the synchronizing information recorded in push-pull is now increasingly used in West Germany; it is included in the present Deutsche Industrie Norm, or D.I.N., standard, and information about it was published in Britain, by the same author, more than a year ago. The 1962 paper in this volume, excellent though it is, therefore now tends to give a misleading impression of the state of these techniques even in West Germany alone. Survey papers are perhaps particularly open to the risk of being overtaken by events, but

some of the theoretical papers in this collection also appear to be somewhat dated.

It must, therefore, be borne in mind that this volume is a record of material that was presented in 1962, some of it not written specifically for international publication, some of it not, perhaps, entirely new at the time. With this proviso the book can be recommended as an interesting and valuable record of the situation in 1962 over a wide range of magnetic recording activities. The publication is of particular interest because it makes available papers from a number of technical authors in the East European countries whose work is not too well known in Britain or the United States.

H. DAVIES

## GLASS-CERAMICS: A NEW TECHNOLOGY?

Glass-ceramics

(Non-Metallic Solids: a series of Monographs, Vol. 1.) By P. W. McMillan. Pp. viii+229. (London and New York: Academic Press, 1964.) 47s. 6d.

GLASS has been very neatly defined as "an inorganic product of fusion which has cooled to a rigid condition without crystallizing". No such succinct definition of a ceramic has ever been formulated and we fall back on a rather unwieldy description of a heterogeneous, polyphase material, based essentially on oxides, consolidated by processes of vitrification and sintering to produce a complex of crystals and pores involved in a glassy matrix. It is of course true that modern technology has moved to the production of relatively pure single-phase polycrystalline aggregates of certain oxides, but this is really the tidy end-point of a progressive development rather than a basically new departure. Now, with the advent of the glass-ceramic, the one technology seems to absorb the other, and from the ordinary processes of glass-making emerges a new class of material, conforming exactly to the crystal-glass description of a ceramic, but with many improved characteristics.

Historically, this has its origin in an odd experiment by Réaumur, who in 1739 subjected glass bottles to a prolonged heat treatment in a mixture of gypsum and sand and converted them into opaque, porcelain-like objects, apparently completely crystallized into a radial network of acicular crystals. It was not until the work of Stookey and his colleagues at the Corning Glass Works was disclosed in 1957 that the technological possibilities of this early experiment were revealed. Normally, in the manufacture of transparent glass, every care is taken to avoid crystallization, but for special effects—opal glasses and glasses coloured by colloidal metals—limited crystallization has played a useful part, although perhaps only very small quantities of crystalline materials may be involved. The new technology of glass-ceramics involves the main body and main constituents of the glass, and the resulting product, which is white and opaque, is almost fully crystallized to a grain size usually less than one micron (which is 20-50 times smaller than that in a normal ceramic), and with a complete absence of pores.

The main developments have been made in America at the Corning Glass Works (although it is known that some development has been done in the U.S.S.R.) and most of the work still remains in the journals and in the patent files. Some years ago the Nelson Research Laboratories of the English Electric Co., Ltd., started work in this field and independently produced a range of devitrified glasses of controlled thermal expansion characteristics which could be made to 'fit' various metals. P. W. McMillan, author of *Glass-ceramics*, has been largely responsible for this development, and he has now produced the first book on devitrified glass to be published in Britain. This is a most welcome pioneering effort, and presents, within a modest compass, a very

readable account of crystallization and devitrification and a survey of glass types and nucleating agents for controlled crystallization. The basic requirement is the introduction of submicroscopic catalyst particles into the glass at a temperature below that at which major crystalline phases could grow quickly, and to disperse the catalyst through the glass so that there are a great number of nucleating centres. One of the important catalysts used by Stookey was titanias: McMillan has made a particular study of the use of metallic phosphates.

The glass-ceramic process itself begins with conventional melting and shaping of the glass. It must then be brought to, and held at, a temperature plateau, some 50° C above the annealing temperature, to nucleate, and then brought slowly to a crystal growth plateau which will be some 50° C below the temperature at which the predominant crystal phase is likely to redissolve. Apart from the obvious change in appearance produced by this heat treatment, there is a small (~1 per cent linear) dimensional change, a marked increase in strength and a change in thermal expansion which can be manoeuvred to meet particular requirements.

The mechanical and electrical properties are discussed at some length: strengths up to 50,000 lb./in.<sup>2</sup> are reported, with a notional breaking strain of  $2-3 \times 10^{-3}$ —at least twice that of ordinary glasses and ceramics. Electrically, especially from the point of view of dielectric loss, there is not much to choose between glasses, ceramics and glass-ceramics, but the last can show higher electric strength. Among possible applications, one, in the field of cooking ware, is probably well known to the public, but more importantly there are a number of possibilities in the electrical field, perhaps, very interestingly, in micro-miniaturization.

Little or nothing is said in the book about the economics of the new technology: how far glass-ceramics will invade the chosen field of other materials will depend very largely on this aspect. The book, which is modestly priced by present standards, is the first in a series of monographs on non-metallic solids, a series which is manifestly away to a good start and which, one hopes, will sustain this early promise. N. F. ASTBURY

## NEW RESOLUTIONS FOR BIOCHEMISTS

### New Biochemical Separations

Edited by Dr. A. T. James and Dr. L. J. Morris. Pp. ix+424. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1964.) 83s.

IN recent years there have been a number of significant developments in the methods which are used for the separation and isolation of naturally occurring compounds. The aim of *New Biochemical Separations* is "to provide up-to-date explanations of the most modern refinements in separation techniques and to include experimental data of their application to biochemical problems". The various methods are described by different authors who are experts in their particular fields and who have, in most cases, been responsible for the developments in the technique they describe. Gas-liquid chromatography, thin-layer chromatography and gel-filtration receive particular attention since they have developed most rapidly recently. This volume is not therefore a complete manual of separation techniques, but it is an important contemporary complement to more catholic text-books such as *Chromatography* by Lederer and Lederer and *Separation Methods in Biochemistry* by Morris and Morris.

The first five chapters deal with the application of gas-liquid chromatography to the separation of radioactive

compounds, steroids, alkaloids, carbohydrates, coenzyme A esters, bile acids and amino-acids. In some cases it is helpful or even necessary to convert the sample into more volatile derivatives by esterification, trifluoroacetylation, or silylation before chromatography. Adequate details or literature sources are given for these preliminary steps. It is emphasized that the chromatographic procedure and the nature of the derivative should be varied where possible in order to achieve the maximum degree of separation and certainty of identification.

The use of cross-linked dextran gels for the fractionation of amino-acids, peptides, proteins and polysaccharides is described in two chapters. Thin-layer chromatography has been used for the separation of amino-acids and their *N*-2,4-dinitrophenyl derivatives; full descriptions of the methods are given. The separation of 1-dimethylamino-naphthalene-5-sulphonyl derivatives of amino-acids by thin-layer chromatography (*Experientia*, 20, 559; 1964) may well prove more popular eventually in view of its high sensitivity. The separation of alkaloids by conventional paper chromatography as well as thin-layer chromatography is described in detail and illustrated by numerous tables of *R<sub>F</sub>* values. Although reversed-phase paper chromatography and chromatography on alumina- or silica-impregnated paper have been useful for the separation of hydrophobic compounds, it seems that thin-layer chromatography is proving to be a more powerful tool. This trend is reflected by the inclusion of chapters on the separation of steroids, triterpenoids and bile acids by this method.

The remainder of the book is devoted to the use of various techniques for the separation of lipids especially those containing polar groups. Progress in the lipid field has been inhibited by the paucity of analytical methods. The present accounts of the use of thin-layer chromatography, chromatography on paper impregnated with silicic acid, and counter-current distribution are important, therefore, in view of the increasing interest in the lipid field.

This book is well produced and remarkably free from errors. Contributions from German authors have been translated into English. Literature references up to 1963 are to be found in most chapters. It is to be hoped that further editions will appear from time to time in order to focus attention on present-day trends in an important aspect of biochemistry. D. T. ELMORE

## POISONS IN INDUSTRY AND RESEARCH

### The Halogenated Hydrocarbons of Industrial and Toxicological Importance

By Dr. W. F. Von Oettingen. (Elsevier Monographs on Toxic Agents.) Pp. x+300. (Amsterdam, London and New York: Elsevier Publishing Company, 1964.) 60s.

THE study of toxic compounds is now in an exciting phase. New techniques, biochemical and electron microscopic, are bringing a mass of new information and new ideas are springing up. Because carbon tetrachloride has been studied for such a long time, the application of the new techniques to the lesion following this poison yields results which can be laid against existing knowledge more profitably than for any other toxin. Inhibition of protein synthesis which occurs *in vivo* can be reproduced *in vitro* and shown to be due to a failure of ribosomal function; this can be seen by the electron microscopist as detachment of granules from membranes of the endoplasmic reticulum.

Furthermore, it is becoming clear that there are general reactions to injury at the cellular level which may occur whatever the toxic agent (degranulation of the endoplasmic reticulum is an example). An advancing under-

standing of these reactions sheds light on the organization of the normal cell. The work of Magee in showing that dimethyl nitrosamine is demethylated by enzymes in the liver to form a highly toxic alkylating agent has extended the field of 'lethal synthesis' from a rare event to being perhaps the key to hepatotoxicity.

None of these developments is mentioned in Von Oettingen's *The Halogenated Hydrocarbons of Industrial and Toxicological Importance*, despite the fact that there is an extensive discussion of experimental work on carbon tetrachloride.

Von Oettingen discusses eighteen halogen derivatives of methane, ethane, ethylene and butadiene. Each compound is dealt with in two sections, one dealing with clinical and industrial data, and one with experimental work. The sections dealing with chloroform and carbon tetrachloride occupy one-third of the book. There are more than 800 references for these compounds alone. The juxtaposition of clinical reports with a collection of the experimental work by a worker of great experience, the author of the well-known U.S. Public Health Service Bulletin No. 414, is very helpful. However, in our opinion, this admirable attempt to present both sides of the field carries with it responsibilities to those readers familiar with one side only which the author does not fulfil. There is no attempt at synthesis or critical discussion in either section. This must make the experimental sections heavy going to anyone not familiar with the field. Among a very wide range of references, dealing with older work, as well as with some of the most recent, a number of key papers are missing which will limit the value of the bibliography to the beginner. In the chapter on carbon tetrachloride, there is no mention of the work of Christie and Judah in the section on hepatic cell injury, none of Seneviratne in the section on circulatory changes. There is no mention at all of Oberling and Rouiller's classic electron microscopic studies, or of any other electron microscope work.

However, for the research worker who is acquainted with the work of the past twenty years, the many references to the older work, though unselective, are very useful.

ELIZABETH and A. E. M. MOLMAN

## A LANDMARK IN ARTERIAL PATHOLOGY

### Arterial Disease

By Dr. J. R. A. Mitchell and C. J. Schwartz. Pp. xv+411. (Oxford: Blackwell Scientific Publications, 1965.) 95s. net.

IN his foreword to *Arterial Disease*, Sir George Pickering correctly states: "... this is careful, methodical work on an important subject which comes to a relatively novel, and I think probably correct, view of the nature of the disease. It is beautifully illustrated and presents new knowledge against a background of the old. It should make a substantial contribution to the advancement of knowledge in an important and hitherto poorly understood field".

The contents of this volume are fascinating and presented in a lucid, direct and sound, if, perhaps, slightly authoritarian manner.

A brief introductory outline of the problem and a description of the material analysed are followed by a text presented in three distinct, albeit closely related sections, namely: Part 1, "The Oxford Necropsy Survey" (ten chapters); Part 2, "Arterial Diseases—A Review" (five chapters); Part 3, "Methods" (one chapter).

In Part 1 the authors present, in relation to historical background and to more recent work, their findings in the hearts and/or vascular trees of several hundred patients—both 'selected' and 'unselected' (criteria detailed)—subjected to autopsy at their uniquely situated 'outpatient' hospital which they state has a 90 per cent autopsy rate

on patients who die therein. Their subjects were all more than thirty-five years old. It would have been illuminating to learn something of the state of the arteries and hearts of infants, children, adolescents and young adults in the same population—perhaps the topic for a future report by these authors? The actual years during which their material was collected is not stated. This omission could be of considerable importance to future workers.

The morphology and localization of 'arterial plaques' (precisely defined), the nature and extent of aortic disease, the relationship of myocardial lesions to coronary artery disease, as well as the morphology, incidence and implications of 'large cardiac lesions', distribution and prevalence of coronary stenosis, pathology encountered in carotid and vertebral arteries and structure of thrombi, are described and critically assessed.

Part 2 is devoted to a critical analysis of present knowledge and prevailing theories of the aetiology and pathology of the diseases studied, an assessment of the possible import of individual peculiarities and of those environmental factors at present considered by many investigators to play aetiological parts of greater or lesser significance. An absorbing analysis has been made of the pathogenesis of arterial plaques in man and of the relevance, or irrelevance (for understanding lesions in man), of experimental contributions to the study of arterial disease and particularly thrombus formation. This section is nicely rounded off with a refreshing, stimulating and critical concluding chapter on the implications of all the preceding for those therapeutic régimes which, at present, are widely and often slavishly instituted for myocardial infarction.

Part 3 should prove useful to all those studying arterial supplies to any organ, although, of course, the blood supply to the heart is here dealt with primarily. It provides full details of the techniques used by the authors. Many other writers in this field might have enhanced the value of their own work by providing similar technical details, so necessary if others are to acquire comparable data. In writing this section, then, the authors are to be congratulated.

It should be apparent, at once, that this is an unusual addition to the literature in this field, for it is an absorbing mixture of clinical, pathological and experimental evidence on the nature and possible (perhaps even probable) pathogenesis of that important group of human arterial diseases—namely, the thrombo-occlusive, degenerative lesions—affecting the main arteries of the human body, with particular reference to the coronary arteries and the myocardial lesions.

As for the latter, the authors tacitly assume they are invariably secondary to coronary occlusion(s). This view on the pathogenesis of myocardial necrosis and/or fibrosis has, for many years, been accepted unquestioned by most pathologists and clinicians. My own deliberate hesitancy in blindly adhering to this conception derives from experiences in other fields where massive parenchymal necrosis (of non-toxic origin) is known to occur in the absence of vascular occlusion, for example, nutritional hepatic necrosis. Moreover, there is now some evidence that myocardial infarction may occur—and not rarely—without preceding coronary infarct; the latter may, indeed, be secondary to the myocardial lesion(s) (see *Arch. Path.*, 78, 432 (1964), on "Low Incidence of Coronary Thrombosis in Myocardial Infarction"). Furthermore, since uterine artery narrowing, and even occlusion, may apparently succeed uterine involution after pregnancy, it seems not impossible that involutionary changes in coronary arteries may perhaps also be consequent on 'disuse atrophy' of the actively used 'hypertrophic' myocardium they once supplied. And what better place to question prevailing dogma than in a review of this book which does this so often and so well.

Indeed, this volume should constitute a landmark in the development of our knowledge of these diseases which

must, in a progressively ageing world population, become of even greater importance than they are at present. It provides a long-overdue critical examination of accepted dogma—a 'spring-cleaning' of our thoughts and of the literature on arterial diseases. The facts and arguments, so lucidly presented, invalidate many of the shibboleths used by workers in this field. Thus, for example, dogmatically held views on the relations of fatty streaks to fibrous plaques in arteries are discredited.

The authors are to be congratulated on the directness with which they state their case and views. Whether or not their views are accepted entirely, it is refreshing and helpful, in a field so befogged with hazy thinking, and encumbered by canonical and often obscure statements, to read: "In our view, the thrombogenic concept is the most satisfactory hypothesis [for the genesis of arterial diseases] so far formulated . . ." "There is little doubt that today the emphasis is changing, with thrombosis emerging as the factor of paramount importance in the development of occlusive arterial disease." They suggest that ". . . our knowledge [may be advanced] more rapidly by focusing attention on the circulating blood, rather than on the vessel wall lesions, which may be the result and not the cause of thrombosis"; and finally—"As we have seen, this is a thrombotic disease and, if any relationship does exist between environmental factors and cardiac infarction, we should not try to explain it in terms of 'atherogenesis' but of 'thrombogenesis'."

Full appreciation of this fact-packed, thoughtful and thought-provoking book might, I think, have been facilitated by a five or ten page summary of the main facts and conclusions presented. Also, this analysis would, perhaps, have been enhanced by greater attention to the development of arteries in relation to their diseases and hence by a fuller consideration of the possible roles of arterial remodelling, regeneration and repair in the pathogenesis of occlusive vascular diseases.

Nevertheless, this volume should certainly be of considerable interest to the innumerable pathologists, experimentalists and clinicians who are, to-day, forced to address themselves to this group of diseases, so frequently the cause of premature deaths of mature adults as to constitute the most important man-killer of our time.

T. GULLMAN

## RECENT ADVANCES IN LIPID RESEARCH

**Metabolism and Physiological Significance of Lipids**  
Proceedings of the Advanced Study Course held at Cambridge, September, 1963. Edited by R. M. O. Dawson and D. N. Rhodes. Pp. ix+657. (London, New York and Sydney: John Wiley and Sons, Ltd., 1964.) 147s.

**M**ETABOLISM and Physiological Significance of Lipids comprises the collected papers presented at an advanced study course on "Lipids" held in Cambridge in September, 1963. The contributors include many of the world's leading workers in this field of biochemistry. The range of topics discussed and the wealth of detailed information which the book contains indicate clearly both the enormous increase in interest in the biochemistry and physiology of lipids, which has taken place especially in the past two decades or so, and also the challenging problems at present confronting research workers. It is evident that the advances in our knowledge of lipids with which this volume is concerned owe much to the development of modern techniques, particularly to chromatographic procedures and to the use of isotopic tracer methods for the elucidation of metabolic pathways in tissues.

In addition to the two major sections on metabolism and on the physiological significance of lipids, shorter specialized sections deal with lipid absorption, lipids of

the nervous system and the association of lipids and proteins in biological systems. Brief reports of the contributions to two symposia, one on the fatty acid composition of lipids and another on techniques, are also included.

In the section on metabolism of lipids, the biosynthesis and inter-conversion of fatty acids in animal and plant tissues are discussed by several contributors. In animal tissues *de novo* synthesis from acetyl CoA and malonyl CoA, elongation and desaturation reactions all seem to be involved; in plant tissues there is no direct evidence at present of elongation of palmitate to stearate or of conversion of the latter acid to oleate.

The synthesis of characteristic branched-chain fatty acids by mycobacteria is also discussed. Other papers in this section deal with recent work on the biosynthesis of sterols, triglycerides and phospholipids. The metabolism of phosphoinositides is described and a hypothetical scheme for their possible role in the transport of cations across membranes is presented. Lipases and phospholipases are the subjects of several contributions, and work on the biochemical characterization of these enzymes is reviewed; the recognition of phospholipase activity in tissues and of the enzymic re-acylation of lysophosphatides has raised the question of the physiological significance of these enzymes in the selective turnover of fatty acids in tissue phospholipids.

In papers dealing with lipid absorption, recent advances in the physicochemical aspects of fat digestion and the mechanisms of transport of lipid material across the intestinal mucosa are reviewed; differences are reported in the mode of transport between different species and between different strains of rats.

Papers on the physiological significance of lipids cover a wide variety of problems. The role of plasma triglycerides in fat transport, the metabolism of short- and long-chain free fatty acids of plasma by various species and the difficult question of the part played by lipids in blood coagulation are reviewed. In other papers in this section lipid metabolism in ruminants and the biosynthesis of milk lipids are considered. Fatty infiltration of the liver as a result of nutritional deficiency or following exposure to toxic agents is discussed in two articles and the hypothesis is proposed that inhibition of lipoprotein formation plays a part in the development of fatty liver. Several contributions are orientated towards the more physicochemical aspects of lipids as membrane components, and others deal with the effects of drugs and hormones on lipid metabolism. In a paper on the lipids of bacterial membranes, the isolation of amino-acid esters of phosphatidylglycerol from a number of micro-organisms is described and their physiological function in bacterial membranes is considered.

Lipids of the nervous system are the subject of four contributions which cover biosynthetic mechanisms, the presence of lipolytic enzymes in nervous tissue and their possible significance in demyelination, a review of lipid metabolism in myelin and the lipidoses.

The section on lipid-protein associations includes an extensive and stimulating discussion of the part played by lipids in mitochondrial function.

Those responsible for the organization of this conference on lipids and the editing of its proceedings deserve great praise for their part in producing this excellent collection of authoritative articles. The book is well produced and will be invaluable, not only to biochemists but also to scientists in other disciplines whose interests involve lipids. Each paper includes a useful bibliography together with a summary of the audience discussion which followed its presentation. In view of the great amount of information the book contains and because some aspects of lipid biochemistry are discussed from different points of view by several of the contributing authors, a rather more detailed index would have been an advantage.

G. R. WEBSTER

## CAMBRIDGE MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

By R. DEMBITZER

Administrative Assistant to the Local Executive Committee

THE 127th meeting of the British Association is to be held this year in Cambridge during September 1-8.

Many members of the Association are familiar with Cambridge and many others have taught or been taught or undertaken research here, but as this article tends to cover a wide field it may not succeed in covering all aspects of the meeting or describe those parts of Cambridge to the satisfaction of every reader. For this I apologize.

Members will be coming to Cambridge at a period of turmoil in the University, in the educational world and in man's ideas of the role of science in the future of the country. Cambridge, like most other universities, has been facing the prospects of the post-Robbins legislation with some apprehension, but it appears now that a number of its fears will not be realized. However, the 'brain drain' has undoubtedly alarmed the authorities and the governmental bodies concerned, and the general hope is that as a result there will be better research facilities and more money for departments and their projects. But changes are slow, and some displeasure is being voiced around. On the other hand, the fact that more emphasis is being placed on the need for scientists and technologists to open the door of the future should give the British Association a new lease of life and an urgent *raison d'être*. It might even be possible to hope that the public at large will realize that the right climate for the growth of those strange human beings, 'scientists' and 'technologists', will come about only through the work of organizations such as the British Association.

Cambridge has been an exciting place to live in for the past few years. An unprecedented period of building has changed the face of University Departments and of Colleges, and much has been altered. Many Colleges are struggling for expansion, some more than others, and visitors who knew Cambridge ten years ago would not recognize many of the newer buildings. During the

meeting of the British Association, building will be in progress at Corpus Christi, St. Catharine's, King's, Magdalene, Newnham, which will prevent these Colleges from taking a major part in the reception of members; there is work taking place on an extension for St. John's College and on the kitchens and buildings of Trinity College.

The most notable change, however, has been the growing importance of the research worker. The Bridges Report, an internal enquiry, pointed out to anyone left in doubt the lack of facilities which were available for members of the University who were not also Fellows of Colleges, and some of the Colleges have made great efforts to overcome this and to offer new fellowships. A new graduate College, to be known as University College, will come into being soon to accommodate University officers who do not cover subjects suitable for undergraduate teaching or are on the administrative roll of the University. The University Centre, also a post-Bridges innovation, will offer additional facilities for other members of the University who fall in this group. With the introduction of Clare Hall, Leckhampton House and Darwin College, we witness the growing awareness of the Colleges of the problem of their research students, a class of people who have so far been given a less than justifiable position in the lives of the College. The three institutions named are all private efforts of Colleges acting either independently or in co-operation. This is certainly not the end of this movement.

Besides Churchill College, which was founded in 1959 to cater mainly for the scientist and the technologist, members of the British Association will be able to see the unfinished buildings of New Hall and Fitzwilliam House. There is one argument, however, which is militating against the geographical growth of the University. As the area covered by the University Departments and the Colleges is extended, the students and the staff will have to travel greater distances to reach them, and this

Fig. 1. Fitzwilliam House, University of Cambridge. Courtesy of City Architect's Department, Guildhall, Cambridge

Fig. 2. Part of Sidgwick Avenue site economics and politics building. Courtesy of City Architect's Department, Guildhall, Cambridge

eventually may lead to a 9 a.m.-5 p.m. University, with students cycling to one end of town to reach the University Department for the lectures, returning to their College late to complete their work in the College rooms or library. Though this is an inevitable process, there is hope that it can be contained.

### The British Association and Cambridge

The third meeting of the British Association (it had been founded in York in 1831) was held in Cambridge in 1833 under the presidency of the Reverend Alan Sedgwick, professor of geology. Meetings were held regularly in Cambridge every twenty-five or so years: 1845, 1862, 1904, 1938, and now in 1965. Of the past meetings, possibly the most significant was that held in 1904, because Mr. A. J. Balfour was president during the period of his premiership. Scientists took advantage of the eminence of their president to tackle him on the question of State-aid to the Universities—the beginning of university grants as we know them to-day. The last meeting here was held in 1938 under the presidency of Lord Rayleigh. It was at this meeting that the idea of a quarterly report was instituted; this resulted in the Association's journal *The Advancement of Science* which from May of 1965 is now published monthly.

The organization of the scientific programme of the meeting has changed very little over the years, although the number of sections, which were six in 1833, has grown to fifteen, and prominence is now given to the social sciences equally with the physical and biological sciences. Sociology and education are among the new sections of the Association since it last met in Cambridge.

### Science in Cambridge

The 127th meeting is being held at a time when the country at large is becoming increasingly aware of the need for scientists and technologists. Cambridge scientists have grown in relative terms; there are many more scientists (in the widest sense) now than ever before and they account for almost half the total undergraduate population, but are well over the fifty per cent mark in the graduate and teaching population of the University.

On occasions like this, figures speak clearest. It is difficult to give groupings which will be generally acceptable, as each University and indeed every University person has different ideas of what discipline fits into which grouping, but even so it is interesting to compare the rates of growth:

	TOTAL STUDENTS (ALL SUBJECTS)		
	Undergraduates	Postgraduates	Total
1928/29	5,226	705	5,931
1954/55	6,749	1,185	7,934
1959/60	7,575	1,422	8,997
1964/65	7,701	1,847	9,548

Of the foregoing figures, the scientists represent the following proportions (figures for postgraduates in parentheses):

	I	II	III	IV	Total	Total as % of all
1928/29	202 (41)	1,110 (239)	544 (15)	181 (58)	2,067 (348)	30.5 (48.7)
1954/55	507 (90)	1,620 (407)	714 (60)	198 (59)	1,939 (616)	43.5 (52.0)
1959/60	465 (95)	1,786 (607)	894 (118)	150 (52)	3,295 (866)	43.5 (60.9)
1964/65	2,659 (744)	773 (190)	65 (87)	8,527 (901)	45.8 (53.7)	

Notes: Group I, mathematics; II, natural sciences (including metallurgy, medicine, veterinary medicine); III, engineering and chemical engineering; IV, agriculture (including estate management and land economy).

Science has always been of fundamental importance in Cambridge, and there is little need, one feels, for it to be 'advanced' here, but its extent may still be a surprise to members of the Association. Those coming to Cambridge after an absence of some years, or who have not had the opportunity of acquainting themselves with some of the latest changes in the scientific field, should go round and make enquiries. On the occasion of the visit to Cambridge of such large numbers of scientists, many Departments are taking the opportunity of holding 'At Homes', and members will be welcome everywhere.

New buildings have emerged all over the city. The main development of the arts faculties has taken place on the Sidgwick Avenue site, designed by Hugh Casson and Partners at a cost so far of about one million sterling, and here in the next few years will be accommodated the bulk of the lecture rooms, staff rooms, research facilities and libraries of the arts faculties. On the science side, there has been no such wholesale concentration, but a gradual re-development of the sites is going on and is likely to go on well into the 1970's.

The two main areas of the scientific departments are the New Museum's site (Bene't Street, Free School Lane, Corn Exchange Street, Pembroke Street) and the Downing Site (Downing Street, Tennis Court Road, Downing College, Downing Place). Both sites have considerably changed over the years, but still accommodate more than twenty world-famous laboratories, all cramped for space. On the New Museum's site, during 1959-60 the Shell Co. paid for a four-storey block for the Chemical Engineering Department. The University has lost its only large multi-purpose hall, The Examination School, which has been taken over by the Department of Physics and which is being adapted as further laboratories and staff rooms.

On the Downing site there have been four major additions since the Second World War. The Public Health Laboratory was built in 1950. Close to it is the Veterinary Anatomy building, a pleasant five-storey extension to the older buildings of the Anatomy Faculty. In 1961 work started on the Psychology building, which was completed in 1963, the same year in which appeared the third stage of the Biochemistry building, built with the aid of the Wellcome Foundation.

In the early 1970's Addenbrooke's Hospital will have completely vacated its building in Trumpington Road and moved to the new buildings which are being built in Hills Road. Part of the new site, away from the town centre, has now been open for four years; but the final transition will take another six or seven. Once they have left, there will be a space of about six acres which, it is expected, will become available for re-development for the use of some of the scientific departments. Eventually, it is hoped, all the scientific departments will have buildings as modern and well equipped as the Chemical Laboratories in Lensfield Road and the Engineering Laboratories in Trumpington Street. The Chemical Laboratories were completed in 1960, at a cost of £2.25 million, and offer accommodation for over 200 research students and teaching staff, and class rooms and laboratories for 500 undergraduates. The Engineering Laboratories are still undergoing a rebuilding period and will not be completed for a few years. However, the Department, the largest in the University with a teaching staff of 80, will eventually be able to accommodate 1,000 undergraduates and 200 research students.

Probably the most interesting development in the field of research in Cambridge has been the growth of Government-sponsored bodies which have found a home here, and whose personnel have been involved and are involved only in a tenuous way with the University. The Medical Research Council have several units, of which three will be visited during the meeting, the Applied Psychology Unit, the Microbiology Research Department, which is attached to Addenbrooke's Hospital, and the Dunn Nutritional Laboratory. The Agricultural Research Council have a large unit at Babraham, concerned with animal physiology, and the National Institute of Agricultural Botany own extensive grounds for the testing of new seeds on the Huntingdon Road.

#### Programme of the Meeting

After the presidential address by Sir Cyril Hinshelwood on "Science and Scientists" on September 1, the scientific programme will start on the next day. This consists mainly of the reading of formal papers followed by the discussion on a theme or themes decided on by the various Section Committees. The keynote for the section work is given by the President in his presidential address. About 300 papers are being presented for discussion, and these will receive the attention of a total membership which will approach 3,500.

A random selection of the papers which will be read at the meeting does show that there will be a very great weight on the side of technology, and some of the lectures have such titles as "Technology in a Liberal Education", "The Interaction of Technologies", "Science Pure and Applied", "Automatic Safe Landing of Aircraft in All Weathers", "Technology and the Good Life", "The Cultural Technologist". While it would be irrelevant to sort out the scientific value of one paper from another one, it is likely that one of the most visually exciting talks will be one given by Prof. B. J. Mason, the president of Section A (Mathematics and Physics), who will speak about physics of raindrops and hailstones, accompanied by demonstrations.

In 1961, at its meeting in Cardiff, the Association for the first time held a one-day symposium on the subject of "Food and Population". This was very successful, as it dealt with a theme which had attracted the imagination of

the country at large on the work of the Freedom from Hunger Campaign which had just started. A speaker on that occasion referred to fuel and power being second in importance only to food and population, and this is one of the reasons for a choice of a one-day symposium, which will be held on September 6. Among the speakers will be Lord Hinton, Lord Robens, Sir Harold Hartley, and Prof. H. J. Kruisinga, and the theme which they will be discussing will be taken up by the various sections in their own activities. The main nationalized undertakings and oil companies are coupling this with an exhibition on the resources and need for fuel and power. It will be held in the Union Society and will last for two weeks after the meeting itself.

#### Excursions

An integral part of the meeting of the British Association is to pay visits to many places of interest, both of a scientific nature and of pleasure in the host region. Cambridge will be no exception, and this year more than 138 excursions have been organized.

Cambridge is probably poorer than many parts of the country in establishments of an industrial nature, and East Anglia has traditionally been the granary of England. But the City and the University make up for it very easily by housing a high concentration of research establishments. Among those which will be seen by the members of the Association are the giant industrial complex of Pye's, makers of all kinds of electronic apparatus, some for use in academic research, others for military uses, others for domestic television and radio. Pye's were founded by a Cambridge man, formerly of the Cavendish Laboratory at the end of the nineteenth century, and have now become a household name. The same link with the University is at the origin of the Cambridge Instrument Co., and of Cathodeon, who make electronic instruments, and others. The Fisons Group of Companies have some of their research departments in the area, and members will see the Pest Control Research Laboratories at Harston and the Laboratories at Chesterford Park. The Welding Research Association at Linton, near Cambridge, undertakes research on behalf of more than 300 member bodies and has close connections with the University's own Department of Metallurgy.

#### Young People's Programme

The lecturers who will take part in the programme for the Young People will be Dr. J. E. Gabb (research medical officer of the Institute of Aviation Medicine), who will talk on "Medical Aspects of Space Flights", Dr. F. A. Vick (member for research, United Kingdom Atomic Energy Authority) on "Exploration in Atomic Energy", Prof. Herman Bondi (professor of applied mathematics, King's College, London) on "Gravitation" and Prof. H. J. Eysenck on the "Measurement of Intelligence". The Science Fair, which has become a regular feature of the programme for young people, will be held in Homerton College, one of the best known of the Teachers Training Colleges. Many schools in the Cambridge area will take part and have been working hard at projects which they will display during the week of the meeting.

The two evening discourses, which will be held in the University Senate House, will be delivered by Prof. F. Hoyle, who will talk about recent work in the field of cosmology and astronomy, and Dr. E. B. Worthington on the "International Biological Programme".

Following last year's successful broadcast by Southern Television of some of the talks of the British Association, this year the B.B.C. will broadcast live lectures on four mornings during the meeting. These will be transmitted from the Lady Mitchell Hall, situated in the new complex of buildings on the Sidgwick Avenue site.

Statistics for this article have been obtained from the *University Reporter* and *Cambridge New Architecture* (second edition, April 1965).

## VIRUSES AND TUMOUR CAUSATION

## AN APPRAISAL OF PRESENT KNOWLEDGE

By DR. PEYTON ROUS, For.Mem.R.S.

The Rockefeller Institute, New York

A HOST of viruses have now been found which induce tumours in one way or another, and their number has increased so rapidly of late that the facts concerning them appear well-nigh chaotic. The present time seems right to try to bring order into what is known and then to ask what it may mean for the neoplastic diseases as such. An obvious first step is to try to group those viruses of vertebrates that belong together, as made plain by their production of typical tumours within the living organism. The phenomena witnessed when they act on cells freed from the restraint of the body by cultivation *in vitro* or in other ways will be noticed only where directly pertinent\*.

During half a century of search many viruses have been come upon which start and maintain tumours in chickens, but few have been discovered that do the like in other creatures. They all have this in common: each changes normal cells into neoplastic cells having features which it determines, multiplies within these cells, causing what appears to be their autonomous proliferation, and can be recovered from them in a condition to produce new growths of identical sort in other, similar hosts. They do everything in short that a real cause can do, and hence they can be termed 'comprehensive' tumour viruses. For most purposes, though, 'do-all' seems better, a word sanctioned by usage for more than three centuries, *vide The Oxford English Dictionary*.

"Do-all: One who manages the whole business; a factotum. 1633 D. Rogers Treat. Sacraments II. 7. 'It is conscience which is the do-all in the soule.'"

"1701 Pepys Diary, ed. by Jackson, 1879, VI. 233. 'The Cardinal is the do-all.'"

## The Do-All Tumour Viruses

The first comprehensive virus was procured in 1908 by Ellerman and Bang from the cells of a chicken leukaemia. Their discovery, though soon enlarged through their finding of other viruses causing chicken leukaemias of different sorts, was still-born into the world of knowledge because the leukaemias were not then deemed neoplastic diseases. A little later numerous viruses were obtained from the solid tumours occurring in chickens, typical neoplasms according to the criteria already established through the scrutiny of transplantable rat and mouse tumours. Each of these viruses produced growths of only the sort from which it had been obtained, yet they differed so widely in effect that the yield of neoplasms was various. Not until 1933 was a mammalian tumour virus found—in rabbits by Shope. It causes the benign, epidermal papillomas often present on the common wild American rabbits known as cottontails, trapped in the south-western United States. In 1934 Lucké reported renal carcinomas to be well-nigh epidemic in the leopard frogs of New England, and later he and others described the virus responsible for these notably malignant growths. In 1958, Shope procured another mammalian virus, one causing the subcutaneous fibromas occasionally present on wild Virginia deer.

To most investigators these meagre findings in creatures remote from man seemed to throw little light on the tumour problem; but in 1951 Gross obtained a do-all virus from the cells of a mouse leukaemia. This caused a stir because the tumours of mice had long been the common currency of cancer research, having yielded numerous facts which

proved applicable to the neoplasms of man. Forthwith a host of workers strove to get viruses from 'spontaneous' mouse leukaemias, and now not a few have been obtained, and some from rats as well.

The do-all virus longest and most closely investigated, now known as the RSV, was procured in 1911 from an anaplastic chicken sarcoma (the RS). It acted only on fibroblasts, and throughout more than forty years caused growths of identical sort, and these only. The viruses next procured from fowls also acted only on fibroblasts, yet each had its own determining effect on the character of the resulting tumours, a rifted, intracanalicular sarcoma, for example, in one instance and an osteochondrosarcoma in another. As time went on many other chicken viruses were come upon which affected cells of other types in ways characteristic of them individually, which results in a widely diverse yield of neoplasms.

The frog virus acts only on the convoluted tubules of the kidney, producing carcinomas of a distinctive sort. Often the malignant cells contain 'inclusion bodies', consisting of aggregates of the virus, but nearly as often these are lacking and the growths then wholly resemble classical cancers. The fibromas due to the action of the deer virus on fibroblasts have a morphology so unvarying as to bespeak strict morphological control by the virus. Some of the mouse viruses inducing leukaemia were wholly specific in their effects when first procured, for example, that of Friend which caused only reticulo-endotheliomas, but cells rendered leukaemic by one virus can become superinfected with another<sup>1</sup>, and for this and further reasons the problem of what is referable to each is too complex for present analysis. Very recently epidemics of leukaemia have resulted in great losses of cattle in Denmark and northern Germany, and much goes to show that they are caused by a virus.

The fact that the RSV actuates the RS tumours it initiates was strikingly demonstrated after they had been examined for fifteen years<sup>2</sup>. There then occurred a period of six months during which the growths were remarkably benign and no virus could be obtained from their tissue despite persistent efforts. But after many serial transfers during this period the growths again became actively malignant, recovered the ability to metastasize, and yielded virus in abundance. Titration tests have since shown that changes such as these are determined by the amount of virus the neoplastic cells individually contain, this determining both their aspect and their behaviour<sup>3</sup>. The same general principle holds true of the growths caused by the Shope rabbit virus, though their morphology is not affected. It elicits papillomas more slowly after partial inactivation by heating, and these lol along even when becoming big, and they frequently regress.

Needless to say, the role of the do-alls must be cyclic under natural conditions, else they could not continue to exist. Spontaneous sarcomas resembling the RS occur sporadically, and they yield viruses related immunologically to the RSV; but how this latter can maintain itself is still a problem, so sensitive is it to inactivation. The same holds true of the virus causing the peculiar chicken sarcoma rifted with blood sinuses, this growth reappearing spontaneously on a single occasion a few years after it was first observed. In contrast the Shope virus causing papillomas is so hardy and so readily transferred from rabbit to rabbit that growths due to it are abundant in several regions where cottontails are

\* No references will be cited to familiar papers, but only to those reporting overlooked facts or such as deserve special stress in the present connexion.

numerous. The renal cancers caused by the frog virus have remained almost epidemic in the leopard frogs of New England ever since they were first noted thirty-one years ago, but no one has yet ascertained how the virus is transmitted. That of the deer fibromas passes from one animal to another by way of the trees against which they rub. A few viruses of the leukaemias of rodents reach the young through the placenta or the milk, but how the generality is transferred has still to be found out.

Do-all viral agents capable of causing tumours of several distinct sorts of chickens have occasionally been come upon, but in most if not all instances they owe their ability to the association of several viruses of differing neoplastic potentialities. In 1917 a 'lymphoma complex' made its presence plain in White Leghorn chickens raised under crowded conditions in the Middle West of the United States, and it gradually caused such huge losses that a government-supported Regional Poultry Research Laboratory was set up in 1937 to combat it. The complex is indigenous to the White Leghorns and it consists of mingled viruses which individually cause leukaemias, lymphomas, several differing sarcomas and two diseases which are not neoplastic. Each of these agents elicits antibodies; yet still the complex cannot be controlled, and it is now prevalent in White Leghorns and chickens of some other kinds from Maine to California.

Each do-all virus has a single species as its natural habitat, and though it may cause growths on inoculation into closely related animals it fails to maintain itself permanently in them. The RSV, for example, is capable on test of producing tumours in pheasants, turkeys and ducks, but it never does this under natural conditions. The Shope papilloma virus, so readily transferred in cottontails, very occasionally causes a growth in one of the many jack rabbits living among them, but it gets no further in this species. Nor is it found in swamp hares, snow shoe and domestic rabbits, though it causes vigorous papillomas in them all on inoculation. The frog virus is indigenous to leopard frogs only. The deer virus produces growths in no other herbivora, and the rat and mouse leukaemia viruses cause growths spontaneously only in these creatures.

#### Do-All Viruses causing Successive Neoplastic Changes

The two do-all viruses which cause benign tumours are capable of more besides this. They can bring about secondary carcinomatous changes in the cells of these growths.

*The papilloma virus.* Very occasionally a Shope papilloma procured from a trapped cottontail has in its midst an epidermal carcinoma which has taken off directly from its virus-infected cells. This happens much more often in the exuberant papillomas induced by inoculating the virus into domestic rabbits; and in these it occurs relatively soon, and the cancers are often multiple. They, like the papillomas, can be serially transplanted\*.

The papillomas are strikingly similar in morphology whereas the derivative carcinomas are widely various. Occasionally one of them seems to differ from the benign growths only in being disorderly, aggressive and metastasizing, but thence their diversity ranges all the way to complete anaplasia, and even those appearing papillomatous on first arising tend to become anaplastic eventually by consecutive, step-like alterations such as are not infrequently observed to occur in human cancers. Owing to their derivation they are now called the Vx carcinomas. Seven of them have been transplanted serially and great efforts have been made to procure a 'cancer virus' from them, but none has been obtained. This failure is the more impressive because six of the seven have yielded the papilloma virus. The growth from which it has never been got (the Vx2, now in its 27th year of serial transplantation) contained the powerful antigen of the papilloma virus throughout its first 3.5 years of maintenance, its rabbit hosts proving completely resistant on inoculation

therewith, but after 4.5 years more not even this sign of it was left\*. Since then the animals carrying the tumours have regularly proved, on inoculation, as susceptible to the virus as normal animals. In contrast the Vx7 (now in its 18th year of maintenance) has continued to harbour recoverable papilloma virus, and this has recently been obtained from its tissue in such quantity as to have been chemically purified by a method that has consistently failed with extracts of the Vx2 (ref. 6). Like this latter it has been completely anaplastic from the first.

These findings make plain that the papilloma virus acts only to initiate the secondary carcinomas it induces, although on occasion it persists in them long. The Vx2 is now generally regarded as a cancer of the classic sort because no causative agent can be demonstrated in it, and as such it is widely utilized for experiment. Not so with the Vx7. Requests for it are few because it still harbours the papilloma virus.

*The milk virus of mice.* A virus first recognized in 1936 as existing in the milk of certain strains of mice is only now mentioned because of features that have been deemed to set it apart. Actually it is the most successful of the do-all viruses because transferred from mother mice to their offspring in the first milk they receive and in this way passed on to generation after generation. Indeed, it can only be avoided if the young are wet-nursed from birth by mice of a strain from which it is absent. It does not manifest itself in the young receiving it until they are adults, and in them only if hormonal and nutritive conditions are right. It then causes tiny growths in the mammary glands of females, doing so even if the surrounding tissue of the same kind happens to be undergoing involution. The little growths—equivocally termed 'hyperplastic nodules'—are actually true neoplastic entities\*, not only in morphology but also in their ability to proliferate serially if freed from the glandular tissue hedging them about, and transplanted to favourable sites in other mice\*\*\*. They are 'conditional adenomas', dependent for success on influences promoting their growth, as are not a few other neoplasms, notably certain cancers of the human prostate. Whether they are left *in situ* or transplanted, carcinomas take off from them often. In this way they become responsible for the frequency of mammary cancers in mice carrying the milk virus, and the more effective this latter is, in causing adenomas, the more frequently do malignant growths arise from them\*. The adenomas are all alike in mice of the same strain, whereas the cancers are even more various than those deriving from rabbit papillomas. In both instances uniformity is succeeded by diversity.

The milk virus elicits a distinctive antibody when introduced into adult mice of strains previously lacking it, yet it never calls forth any in mice receiving it when new-born, a fact understandable in terms of immunological tolerance\*\*\*\*, and of immunological paralysis later because of its continued presence. This being so, one might suppose that the conditions would be right for the recovery from the carcinomas of some related, derivative 'cancer virus', yet these have never yielded anything except the milk virus, which may ride along in their tissue throughout years of serial transplantation, only to be lost eventually. Its scope of action is exceedingly narrow. In no other species have the adenomas or a causative virus with similar attributes been found\*.

In sum, the milk virus is like the papilloma virus in causing benign tumours from which cancers arise and resembles it further in serving as no more than an initiator of the malignant growths.

\* The milk virus, when first discovered, seemed to provide a lead to the causation of mammary cancers in women, but no preliminary 'hyperplastic nodules' have been present in their breasts or in those of rats or rabbits, animals that also have mammary carcinomas. Furthermore, the incidence of these growths in women has given no indication of any noteworthy familial tendency to them, and the most ardent search, with the electron microscope, of normal and malignant human mammary tissue has failed to disclose any virus particles although those of the milk agent of mice can be readily seen by means of this instrument.

### The Disclosures provided by the Do-All Viruses

The number of do-alls is small, their limitations are great, and they are a motley lot, yet they have revealed some fundamental facts. They first enabled investigators to perceive how secretly a virus can act to cause tumours, producing growths which, both in appearance and behaviour, seem intrinsically cellular. A reciprocating partnership between cell and virus has been found to exist, as has also an exquisite, host-within-a-host relationship of virus, cell and organism. Two types of immune reaction by the body have been brought to light, one directed against the tumour cells as such, the other against the virus, both of them frequently present together when a tumour fares badly in a new host. The do-alls have also provided examples, resembling those in man, of the two differing ways whereby normal cells attain to the cancerous state, namely, by a direct, one-step change, or by two steps, the normal cell first becoming a benign tumour cell and later a malignant one by further discontinuous alteration.

In sum, what is known about the do-alls would enable one to understand how every tumour could be caused by a virus if all were produced by agents having their capabilities; but much speaks against any such assumption, as will be made plain farther on.

### The Synergistic Effect of Associated Do-Alls

Certain changes that have recently taken place in the virus causing the RS chicken tumour have large interest as disclosing what can happen to a do-all in the course of time.

Throughout almost half a century the RSV, though often tested, produced only sarcomas and these in fowls. Then in 1957 Zilber reported that it would cause haemorrhagic cysts as well on inoculation into newborn rats, and fibromas in new-born rabbits<sup>11</sup>. Soon afterwards he and some Scandinavian investigators showed that it would give rise to lymphomas also in young rats and mice, and that in new-born Syrian hamsters, cotton rats, guinea-pigs, ferrets and monkeys of several sorts it would cause sarcomas resembling the typical RS<sup>12-14</sup>. Now every strain of the RSV maintained in America and Europe has been found to produce such tumours in rodents.

What is the reason for the new capabilities of the RSV as observed in these widely separate lands? One can scarcely attribute them to a sudden burst of widely effective virus variants after the lapse of nearly half a century during which only a few had been procured, and these of limited effect in fowls<sup>15</sup>. Recent collateral discoveries tell much. Throughout decades no sign was found of contagion when chickens carrying the RS were purposely kept crowded in coops together with normal fowls. Even when the tumour tissue was repeatedly fed to these latter in quantity, growths failed to arise. Yet a few years ago Burmester, of the Regional Poultry Research Laboratory for study of the lymphoma complex, reported that pullets cooped with adult chickens carrying RS sarcomas not only developed these in their subcutaneous tissue but visceral lymphomas as well<sup>14</sup>. He had previously found that fowls carrying viruses of the complex often appear healthy, and this though the agent causing visceral lymphomatosis is transmitted to them both by contact and through the egg, as he had already shown<sup>14</sup>. Now his further experimentation made plain that the 'contagiousness' of the RSV is due to association with it of this other virus<sup>16</sup>. Yet here was not merely an instance in which each of the two agents produced growths characteristic of it in the same chicken. The lymphoma virus had so empowered the RSV that it was really contagious, causing typical RS sarcomas in normal chickens. More recently some California workers, purposely utilizing Leghorns known to harbour the lymphoma complex, have shown that virtually all the agents in this category can help or hinder the oncogenic action of the

RSV. Incidentally they expanded a finding already mentioned here, showing that chick embryos are very often infected with one virus or another of the complex, a fact of importance in relation to the utilization of such embryos to prepare vaccines.

The history of the introduction of the lymphoma complex into Europe provides additional support to the supposition that the new ability of the RSV to cause tumours in mammals is due to a synergistic association with it of the agents of this complex. Andrewes, working intensively with the RS and other chicken tumours from 1926 until the Second World War, sought leukaemias in English fowls, and lymphomas such as the complex causes, but found none<sup>17</sup>. American poultry records show that White Leghorns of a stock known to carry viruses of the complex were imported to Scandinavia a few years prior to the discovery by workers in these countries that the RSV is oncogenic for rodents, and a little later the complex was introduced into England—the last European country from which this new ability was reported. A Swedish worker has recently commented on "the almost omnipresent lymphomatosis virus" in the fibroblastic tissue of chickens<sup>18</sup>. It is now known to be present in the U.S.S.R.

All things considered, one might do well to reserve the term RSV for the uncontaminated virus—which may be isolated again—and to designate as 'RSV' any strain producing growths that indicate another virus is acting with it.

On coming on a new virus we are inclined to take for granted that it has always been what it is when we find it, and not reckon with its past. The RSV has been 'forced', to use a gardener's term, by frequent passage in chickens of many kinds and countries throughout its long propagation. Hence abundant opportunities have existed for other viruses besides those of the 'complex' to join it. Perhaps they have.

### The Viruses Initiating Neoplastic Change

**Polyoma virus.** The ordinary chemical and physical agents known to be capable of inducing tumours in animals do no more than convert normal cells into neoplastic cells which then multiply, forming tumours for reasons still unknown. Several viruses also possess this initiating power. The most enlightening is an exceedingly infectious virus found by Gross in 1951. This agent maintains itself by producing widespread, cellular injury in healthy-looking mice, and if the conditions are right, a few scattered cells amidst the multitude of the injured undergo a change which is its antithesis: they are rendered neoplastic and proliferate as a result, forming tumours which grow progressively and can be maintained indefinitely in suitable hosts. The virus does not act, like a do-all, on cells of only a single kind but on many, which results in widely various tumours—hence its present name, the 'polyoma' virus. Furthermore, its neoplastic capabilities are not limited, as are those of the do-alls, to species nearly related to that in which it is indigenous, but are wide in scope, growths resulting after its inoculation into rats, rabbits, guinea-pigs, hamsters and ferrets. In both these fundamental respects the polyoma resembles the chemical and physical initiators. Like these agents also, and in striking contrast to the do-alls, the virus fails to have any determining influence on the morphology of the tumours it induces. That depends on the kind of cell exposed to it, as in the case of the chemical and physical oncogens. In another, even more significant, respect it often resembles these agents: the virus is left behind as the neoplastic cells proliferate. Its disappearance is usually very gradual, though. Not only do most of the growths that are serially transplanted fail eventually to yield it any longer but sometimes not even an antigenic trace of it remains, although earlier it had elicited antibodies<sup>19</sup>. Now, like the rabbit papilloma virus that

initiated the Vx2, it has failed to persist even as a passenger virus.

The primary effect of the ordinary chemical oncogens is injurious, with neoplastic change as an incidental occurrence. So too with the polyoma virus. When the most powerful of chemical oncogens, 9,10-dimethyl-1,2-benzanthracene (DMBA), is applied to a broad expanse of mouse skin nearly all the myriad epidermal cells exposed to it are damaged, but here and there one of them is converted into a neoplastic cell, which results in scattered growths. The oncogenic action of the polyoma virus is of the same sporadic sort: it never causes any wholesale conversion of cells to the neoplastic state. The initiating abilities of the chemical agents can often be superimposed, which results in a larger yield of tumours than if either had been used alone. Precisely this happens when the polyoma virus is brought to bear on cells previously X-rayed: a much larger proportion of them become neoplastic<sup>10</sup>.

With all these likenesses to the generality of chemical oncogens, there yet remain two basic differences. The polyoma is contagious, infecting whole colonies of mice, and it persists for a considerable time in the proliferating cells it has rendered neoplastic. But these are differences readily understandable in terms of the intimate relationship existing between viruses and cells. Obviously on most occasions the polyoma virus acts as no more than an ordinary chemical initiator of neoplastic change, and chemical indeed it is, though of a distinctive sort as shown by its recent analysis<sup>8</sup>.

Very occasionally the polyoma fares well in the cells it has rendered neoplastic. This was the case in the exceedingly rare tumour from which the virus was first obtained, a carcinoma of the parotid gland. The virus had so flourished in the cells of this neoplasm as to be procured from it in an oncogenic state, and in some other parotid cancers resulting from its inoculation it has fared as well. Evidently the cells of these special growths are peculiar in providing it with a wholly favourable milieu during its sojourn in them, yet it has not undergone conversion to a real do-all virus. When again inoculated into mice it proves oncogenic in the same indirect fashion as before, causing widespread, smouldering, cellular injury with neoplastic changes as a by-product.

Here a fact that is seldom taken into account deserves stressing. The initial neoplastic findings with the polyoma were obtained in animals in which it is foreign, namely, inbred mice of laboratory strains. Its native hosts are house-mice and it exists widespread in these, often causing epidemics in slums, barns and granaries, as shown by blood tests<sup>11</sup>. Tumours never result from its action in them but only the typical, injurious cell disease; and though on access to laboratory mice, animals of distinctively different strains, it produces similar epidemics, with neoplasms as an occasional result, these are so infrequent as not to increase perceptibly the statistical incidence of tumours as compared with the number occurring in the uninfected members of the colony. Though the virus was primarily obtained from a parotid carcinoma occurring in a laboratory mouse, it caused growths only in new-born animals of this kind and only months after inoculation. In new-born hamsters, widely alien hosts, it produces them within a few weeks, and hence its neoplastic effects have been examined mostly in these.

The polyoma provides an extreme instance of Theobald Smith's law according to which a damaging parasite tends to become a symbiont when the relationship between it and its native host has existed long.

**Human initiating viruses.** The fact that the tumours due to the polyoma virus occur incidentally to a chronic, non-neoplastic disease has brought up the question whether similar happenings may not occur in man. So widely various are the many hundred, ordinary chemical oncogens, and so multifarious are the viruses in their capabilities—and uniquely intimate in their relationships

to cells—that it would be strange indeed if no agents of this sort initiated tumours in man.

Actually cancers have now and then appeared at sites where one or another of several well-known human viruses had produced skin injury many years before, leaving behind disordered tissue. These instances of long-delayed oncogenesis, for example the malignant melanomas which occasionally arise amid old small-pox vaccination scars, remind one of the cancers sometimes occurring in aged persons where their skin was burned in youth, as also of those carcinomas occurring in men uncircumcised when young. Not so with the cancers occurring where herpes simplex and herpes zoster viruses have previously produced their characteristic injuries of the skin. Here, epidermal carcinomas have occasionally arisen much sooner than those induced in man by the generality of chemical oncogens—after 6 weeks to 5 years in the case of herpes simplex<sup>12</sup> and 3 months to 3.5 years in that of herpes zoster<sup>13</sup>. The cancers traceable to the effects of herpes simplex have been situated where 'fever blisters' had previously occurred on the lips of ageing people who were unusually sensitive to sunlight. Since sunlight is itself an oncogen it seems likely that the tumours were actually the outcome of co-carcinogenesis.

A great number of other viruses productive of human diseases and residing long in the body have recently been injected into animals to learn their oncogenic possibilities. Because of experience with the polyoma virus, new-born hamsters have generally been used. Out of more than a hundred viruses tested, only three have yielded tumours. All are adenoviruses<sup>14,15</sup>, agents often causing inflammation of the lymph glands and tonsils of young persons, and persisting in their tissues for a longer or shorter period. The growths induced have been mostly "primitive, undifferentiated sarcomas with epithelioid traits", and some have been obtained in new-born rats and mice. They can be serially transplanted in adults, but none has yielded any oncogenic virus, though viral antigens persist within them, as serological tests have shown. Occasionally, remnants of virus particles can be perceived in the tumour cells with the electron microscope<sup>16</sup>.

A virus of rhesus monkeys, termed SV40, which does no more than produce vacuoles in their renal cells when cultivated *in vitro*, also induces tumours in new-born hamsters, but not in adults, though the tumours can be propagated serially in these. At times they yield a little oncogenic virus, and again none at all, though still containing viral antigens<sup>17,18</sup>.

Obviously the conditions under which the adenoviruses and SV40 give rise to tumours are exceedingly unnatural. Not only are the viruses introduced into sucklings of a remote species, but also the injection is done at the time when immunological tolerance is readily evoked, as witness the findings with the milk virus, and under such circumstances they soon become safely ensconced. For viruses very swiftly become fixed on living cells of the kinds susceptible to them, and these protect them from such circulating antibodies as they may subsequently call forth from their hosts<sup>19</sup>.

At this writing more than fifty viruses have been procured from rhesus monkeys, but none native to these creatures has caused genuine tumours in them, nor have any been obtained from the growths arising spontaneously in hamsters.

#### The Combined Effects of Tumour Viruses and Ordinary Chemical and Physical Oncogens

The increase in neoplastic changes when the polyoma virus is brought to bear on cells previously X-rayed is not the sole instance of the joint effect of tumour viruses and ordinary chemical, oncogenic agents. When areas of scarified rabbit skin were exposed to the oncogenic hydrocarbon DMBA, during the few days of healing after inoculation with the Shope virus, papillomas completely resembling those ordinarily caused by this agent arose,

but they underwent carcinomatous changes much sooner and oftener than did control growths on the same rabbits; yet the DMBA had, as usual, been injurious to the epidermal cells exposed to it while they were proliferating to cover the scarified expanses of skin. As a result the papillomatous layer formed very slowly and remained much more shallow than that of the controls. Nevertheless, carcinogenesis was hastened and rendered extraordinarily frequent<sup>24</sup>.

Recently, several human viruses ordinarily non-neoplastic, notably that of *herpes simplex*, have been found to induce tumours in mice previously painted with one chemical carcinogen or another in an amount too small to be oncogenic in itself<sup>25,26</sup>. The carcinomas thus induced have been of various sorts, like those due to the generality of chemical initiators.

### Effect of Do-All Viruses on Neoplasms actuated In Ways Unknown

The Shope papilloma virus has remarkable effects on the benign papillomas induced by tarring the skin of domestic rabbits. The growths differ distinctively in morphology from those caused by this agent, yet they have the typical character of neoplasms. After intravenous injection the virus often localizes in the benign tar tumours, resulting in very rapidly enlarging, mongrel growths, composed of cells that exhibit individually the merged morphological traits of the papillomas due to these differing oncogens. The virus has similar effects on many of the carcinomas which result from tarring cottontail rabbits. When small pieces of the cancerous tissue are returned to the donor animals, after exposure *in vitro* to a virus suspension, not only do their cells proliferate with prodigious rapidity, as compared with those of control grafts, but also they are now much more aggressive, and the morphology of the resulting tumours undergoes marked alteration. The virus has again acted not only as a synergist but as a transforming agent<sup>21</sup>.

The findings have been very different when the RSV was injected into the bloodstream of chickens carrying anaplastic sarcomas induced with tar or with the polycyclic hydrocarbon, 3:4-dibenzanthracene (DBA)<sup>22</sup>. The morphology of these tumours—which differ slightly yet distinctively from the RS—underwent no alteration, nor did their growth-rate change. Yet the RSV had become associated with them as shown by its recovery from the tumours of a second serial transfer. Here it may be recalled that the anaplastic Vx7 has never shown any sign of the formative influence of the papilloma virus, its constant companion; nor indeed have such tar carcinomas of cottontails as were anaplastic when experimentally infected with the virus. It may well be that such simplified growths no longer possess the power to assume the papillomatous form.

### Recovery of Extraneous Do-All Viruses from Tumours of Unknown Cause

Recently several investigators have procured leukaemia viruses by extracting the tissue of solid mouse and rat tumours long maintained for experimental uses and of unknown cause, notably the Ehrlich carcinoma, now sixty years old. This finding was the more surprising because the animals carrying the growths did not themselves have leukaemia. Yet a reasonable explanation lies at hand. Many non-neoplastic viruses are known to become associated with tumour cells, which thereafter protect them, as already stated<sup>27</sup>, from circulating antibodies, with the result that they persist as passengers. That the barrier interposed by the cells can act in both directions was clearly proved by a continuance of the tests just described which showed that the RSV was present in DBA tumours without giving any sign of itself. Some of the growths resulting from a third transfer of these growths regressed and wholly disappeared, and at the sites where this had happened typical RS tumours arose, obviously because

the RSV was no longer held in check but set free to act on the adjacent fibroblasts, elements which are especially susceptible to it during reactive proliferation<sup>28</sup>. It may well be that stray particles of leukaemia virus had become associated with the cells of the tumours of unknown cause and were restrained by them from producing disease, even after multiplying to a potentially pathogenic amount.

Persistent efforts have been made in the United States to find viruses which would lodge in human tumours and destroy their cells. Some have been procured: but they have killed normal tissue cells as well. No sign has been obtained that any tumour of man has been abruptly invigorated or transformed during its course, as happened when the Shope virus infected the tar tumour of rabbits. The paradoxical fact should here be mentioned that the Vx7 carcinoma, though carrying the papilloma virus in a potentially active state, has grown only about half as fast throughout the years as the Vx2 and almost never metastasizes as this latter usually does.

### A Grouping of the Neoplastic Viruses

When the tumour viruses are viewed together it can be seen that nearly all belong to one or the other of two basically different categories, with a few bridging instances between. The viruses of the do-all group exist in a perfect partnership with the tumour cells they maintain as 'autonomous'; whereas the initiating viruses have no such actuating role but resemble the ordinary chemical and physical oncogens in their effects.

The polyoma virus has the role of an initiator when producing tumours from which it entirely disappears, but it also provides enlightening intermediate instances. As already stated, it causes no tumours in the wild house mice to which it is indigenous but only the widespread, injurious, cellular disease characteristic of it, whereas in mice of laboratory strains it induces sporadic neoplastic changes in addition. Only rarely is it obtained in an oncogenic state in the tumours it thus starts off, and then it has not become a do-all but brings on the same zigzag course of events as previously, producing cellular injury, with neoplastic changes as a by-product. If the resulting growths are long maintained by serial transfer, the polyoma ultimately disappears from them, not even an antigenic trace remaining<sup>19</sup>.

The tumours initiated by the adeno- and SV40 viruses in new-born hamsters provide intermediate instances of a simpler sort. Again as has been stated, the growths induced by adenoviruses fail on serial propagation to yield these agents in an oncogenic condition, though antigenic traces of them persist and sometimes remnants of virus particles<sup>29</sup>. The SV40 virus also tends to disappear during serial transfer of its tumours, but it leaves behind an antigen, and occasionally a little oncogenic virus<sup>30</sup>.

Now for a telling fact. The tumours due to all three of the bridging viruses continue to grow as actively as ever while these agents are undergoing drastic reductions in pathogenic ability and are disappearing more or less completely. Sometimes those due to the polyoma virus grow even more vigorously<sup>31</sup>. This being so, it is difficult to suppose that their influence has exceeded the initiatory. Indeed, one may question whether the polyoma virus has really an actuating effect on the cells of the few tumours in which it flourishes or merely multiplies within their cells because these provide it with a notably favourable medium.

The chief difference, needless to say, between the bridging initiators and the chemical and physical oncogens in their oncogenic relationship, is that the latter have no ability to increase in quantity and ride along in the cells rendered neoplastic by them.

Two of the do-alls, the rabbit papilloma virus and the milk virus, serve as initiators on occasion, but their role in this respect differs markedly from that of the generality of such agents. Instead of acting on normal cells they

bring about carcinomatous changes in the cells of the benign tumours they have already engendered. Though they sometimes persist throughout long periods in the resulting cancers, as happens in the case of the Vx7 and many of the mammary cancers that take off from adenomas, they may ultimately be lost, as in the notable instance of the Vx2. Their role is solely that of initiators; and so too, in all probability, is that of the herpes viruses in bringing about carcinomatous changes in the injured cells of the epidermal lesions they produce in man.

### What can be the Meaning of the Neoplastic Viruses?

The many facts assembled here bring home a striking truth. Except in chickens, neoplastic viruses are exceedingly rare. Very few mammalian do-alls have been found since 1911, and almost as few that act as initiators. This is the more remarkable because, as already pointed out, viruses are so intimately associated with cells and so numerous and diverse in their effects on them.

Any attempt to consider the generality of mammalian tumours in terms of present virus knowledge can be no more than tentative because what viruses are and do has consistently transcended expectation. They were long regarded as tiny bacteria differing from the usual only in that they were most exacting in their nutritive requirements. Not until the 1930's was their obligate association with cells perceived, and only later was it realized that these are their chemical workshops. What a hubbub of surprise and of surmises about the nature of life followed on crystallization of the tobacco mosaic virus! When a study by highly qualified geneticists of what seemed an inherited tendency to breast cancer in mice led on to the discovery of the milk virus, this astounding possibility had not even entered man's thought! Perhaps to-morrow some cleaving discovery on the causation of tumours by viruses will demolish the inferences of to-day; yet what we now know would be worth little if none was made.

On marshalling the neoplastic phenomena which must be understood, whatever their cause, one is confronted with the vast, multifarious array of mammalian tumours initiated by ordinary chemical and physical oncogens. Can it be that most of these growths are actuated by hidden do-all viruses? None of the innumerable efforts to procure such agents from them has succeeded save in dubious instances. Perhaps the techniques of search have been inadequate, a view fostered by the outcome of recent experiments in which mice with their resistance weakened by irradiation developed viral leukaemias. But in this connexion the fact should be recalled that solid rat and mouse tumours, long maintained by serial transfer and of unknown aetiology, sometimes yield a lurking leukaemia virus on extraction, though their hosts had been free from this disease.

Efforts to get actuating viruses from mammalian neoplasms arising 'spontaneously' have also drawn a blank save in the case of the rabbit papilloma, deer fibroma and some mouse and rat leukaemias. Not so with the spontaneous chicken tumours. A do-all virus has been procured from every one of these that could be maintained long enough for adequate test. Since this is the case, one might suppose that chicken tumours induced by chemical oncogens would also yield viral agents. But not so! Though they closely resemble spontaneous growths in all essential particulars, a virus has almost never been procured from them. This paradoxical state of affairs is peculiar to fowls, as is also the prevalence and wide distribution of a lymphoma complex.

There is a more substantial obstacle than failure to obtain viruses to the assumption that such agents may be the actuators of the generality of mammalian growths, namely, the need for a perfect partnership between cells and virus if the latter is to function enduringly in this

way. The gradual disappearance of the polyoma virus from all except a few of the tumours it has initiated well illustrates this need, as does also the dwindling and loss of the SV40 and adenoviruses from the tumours they have started off in hamsters, animals to which they are strange. The cells are the stronger party in these imbalances, remaining vigorously autonomous like those initiated by ordinary chemical oncogens. The do-alls are the only viruses known to maintain the neoplasms they induce, and since each of them causes tumours of only a single sort—and in a single species under natural conditions—one would have to invoke a microcosm of these agents to account for the macrocosm of tumours which arise spontaneously in a single mammalian species, and different microcosms for such species as are not closely related.

This does not rule out the possibility that a few human tumours may be caused by do-alls. The electron microscope has recently disclosed in the blood of certain leukaemic patients particles which have a peculiar form much like that of the viruses causing some mouse leukaemias. Yet even if viruses turn out to be a cause of this disease in human beings, and perhaps of a lymphomatous neoplasm (Burkitt's disease)—now killing children in Africa—this limited finding cannot be regarded as an Open Sesame to the cause of the generality of human growths. It certainly has not proved to be such in mouse, rat and rabbit.

There are other possibilities. The 'RSV' of chickens, when acting together with a lymphoma virus, produces tumours of several sorts in rodents. Similar synergistic associations of mammalian viruses, which result in a widening of their effective oncogenic range, may conceivably occur, though no sign of any such happening has been found in man.

The fact that certain viruses, some of them oncogenic, disappear from view with the electron microscope for a brief period soon after entering cells—'go into eclipse', that is to say—has made it tempting to suppose that the generality of tumours, however induced, may contain causative viruses that remain undisclosed by any present means of demonstration. The rabbit papilloma virus provides a suggestive instance in point, being seldom recovered from the vigorous growths it causes in domestic rabbits. Indeed, it cannot be seen even with the electron microscope in cottontail papillomas which are actively proliferating, although they yield it in abundance. Only after the cells stop dividing and begin to differentiate into squamous elements does it become perceptible. Can one suppose that viruses actuate most, if not all, of the tumours of unknown cause yet remain permanently invisible? To imagine this is to come up against the jolting fact that nearly all of the oncogenic viruses now known elicit readily recognized, specific antibodies which make their existence known. Even when no virus can be seen or got from the rabbit papilloma it calls forth a strong antibody bespeaking its presence.

Needless to say, initiating viruses may exist in man which have not been discerned as yet. Serological tests have shown that one of the adenoviruses causing tumours in new-born hamsters exists widespread in Britain, and on isolation it has again produced hamster growths. In several human tumours excised in the United States adenoviruses have also been found; but their finders concluded that they were probably mere passengers in these growths. The ordinary maladies which have given the adenoviruses their name occur mostly in young persons; yet statistics show the incidence of cancer to be at its lowest during adolescence, and it undergoes no substantial increase until after the mid-thirties. Nevertheless, the possibility remains that the adenoe, like the herpes viruses, may occasionally engender a tumour, though one arising after a much longer time. In appraising the importance for cancer causation of such presumptive happenings, one should keep in mind the heavy loss of human life resulting from the misdeeds

of glands secreting hormones in pathological amounts. In comparison with their effect, what viruses may do seems negligible. Certain hormones not only initiate tumours but also drive them on. Some years ago Huggins discovered that not a few prostatic carcinomas are dependent for their entire existence on the male sex hormone, and that if its influence is excluded or nullified by means of a female hormone, the growths may dwindle and vanish even though they had metastasized<sup>17,18</sup>. Here is extraneous actuation, in which a virus can have played no part, in contrast to the intracellular effect of the do-alls.

The fact that the rabbit, deer and frog do-alls are directly transmitted from one individual to another under natural conditions, resulting in tumours, leads one to ask whether the recorded incidence of human growths yields any data suggesting a similar transfer of neoplastic viruses. Save in the debatable case of Burkitt's disease, statistics speak convincingly against any such happening—a most fortunate, bed-rock fact because maladies due to viruses so occupy public thought to-day. With cancer destructive to almost one person in six, and arising in numerous others who are saved in one way or another, it inevitably happens that now and again it will manifest itself in several individuals who have lived in the same locality or house. Chance accounts entirely for this, yet the fear of contagion persists in not a few persons. Seldom is the fact considered that throughout the long history of civilized man, huge, comprehensive tests which bear on this very possibility have unwittingly been made through the crowding together of hordes of human beings in army camps, ghettos, almshouses, prisons and the like. The dread of communicable diseases was far greater in old times than now, keeping the acumen of medical men whetted and quarantines rigorous; yet no reports of any unusual prevalence of tumours in people living cheek by jowl have come down to us from out of the past. Many epidemiologists in recent years have made a world-wide search for places or societies in which cancer has seemed exceptionally frequent, and not a few have been found; but always they have been traced to the action on the human body of chemical or physical initiators—exerted sometimes through living agents, for example, the tubercle bacillus and the *Bilharzia* parasite—or else to abnormal, genetic susceptibility to oncogens, as in the instance of the unfortunate 'moon children' frequent in an inbred tribe of Central American Indians, albinos who mostly die of epidermal cancers if they live long enough for tropical sunlight to have its carcinogenic effect on their unpigmented, naked skin<sup>19</sup>.

The investigation of viruses has revealed nothing whatever so far about the actual character of the changes cells undergo when rendered neoplastic, and though the do-alls are responsible for the independent behaviour of the cells in which they multiply, how they affect these remains unknown. The reason why cells act in an autonomous way after conversion to the neoplastic state by oncogens which merely initiate, including certain viruses, is also still conjectural. So, too, is the reason for the discontinuous, irreversible steps whereby neoplasms sometimes go from bad to worse. Our ignorance in all these matters stares us in the face.

In 1961, 326 American scientists<sup>20</sup>, as also many elsewhere, were known to be working on the tumour viruses. Their number is greater to-day. Why should there be this huge concentration of effort on so meagre a material? It is because numerous men of keen ability and specialized knowledge of widely different kinds have lately come to realize that even a single tumour virus offers unique opportunities for discovery. Study of some of the destructive viruses, those producing precise cell injuries, can be rewarding because one can learn through them, by way of the lesions they cause, the function of this or that item of cell equipment. But the tumour viruses offer vastly more in conferring an independent, aggressive life on

cells. No matter that this life is pathological: to learn about the normal by inducing the pathological has long been a prime stratagem of investigators. The tumour viruses provide instances of this sort ready-made. Hence most of the new workers give little thought to the problem of tumour causation in relation to what it now means to man. They are bent on learning how normal cells become neoplastic and proliferate independently. It may well be that through what they ultimately discover tumours can be fought with an understanding of them. The minority of virus workers, those who view tumour causation in its practical aspects, have a more immediate task. Confident, through knowledge already gained, that neoplasms seldom if ever arise 'spontaneously', that nearly all are occupational diseases of the body acquired while running the gauntlet of life, they are eager to learn more about why tumours occur, and among other questions they keep asking themselves what roles viruses have in causing and maintaining these. The intermingling of the facts newly won by the two sets of workers, the 'hows' and the 'whys' as one might call them (and fortunately some are of both sorts), is not really chaotic but powerfully evocative of thought and venture.

No one can tell what change or experiment may next reveal as concerns tumour causation. As William Blake once wrote: "To the man of imagination Nature is imagination itself"<sup>21</sup>.

## OBITUARIES

## Sir Edward Bailey, M.C., F.R.S.

SIR EDWARD BAILEY, a former director of the Geological Survey of Great Britain and the Museum of Practical Geology, also for seven years previously professor of geology in the University of Glasgow, died in London on March 19, at the age of eighty-three.

The range of his international reputation may be gauged from his election to foreign membership of the national scientific academies of Belgium, Norway, Switzerland and the United States. This reputation mainly stemmed from his investigations over a long period in the south-western Grampians and Inner Hebrides, where he played a prominent part not only in explaining the complicated sequences and the repetition of rock types in schists, but also in unravelling the succession of events in ancient volcanic episodes. Much of his work in other fields, though less well known, proved equally stimulating. His strongly developed sense of the heroic, however, brought praise from some but impassioned criticism from others.

Edward Battersby Bailey was born at Marden in Kent, where his father was a medical practitioner. When the family moved to Kendal, Bailey attended Kendal Grammar School, whence, in 1899, he won an open scholarship to Clare College, Cambridge. There he showed outstanding ability by achieving first-class honours in both geology and physics in Part II of the Natural Sciences Tripos in one year (1902); also in that year he joined the Scottish branch of the Geological Survey of Great Britain. This service with the Geological Survey had two interruptions: the first between 1915 and 1919, when Bailey served with the Royal Garrison Artillery and was severely wounded on the Somme in 1916, and again near Ypres in 1918; he was awarded the Military Cross and the French Croix de Guerre with palms, and he was made a Chevalier of the Legion of Honour. At the close of 1929 he left the Geological Survey for the geology chair at Glasgow, which he relinquished in March 1937 to return to the Geological Survey as its director, an appointment which he held for eight years, culminating in his knighthood.

In his book *The Geological Survey of Great Britain* (1952) Bailey recorded his enjoyment on joining the Geological Survey at such an invigorating centre as Edinburgh, for he realized that he was to research "among a jostling crowd of problems awaiting solution". Having acquired at school and at his university extraordinary physical strength and mental courage, he became dedicated to geological problems and his alert mind brought insight to them. His flair for original thought was aided by a skill in reassessing and building on the observations made by others. He soon succeeded in clarifying the Carboniferous volcanic history of the Campsie Fells in Stirlingshire. In Argyllshire, with O. T. Clough and H. B. Maufe, he demonstrated in 1909 that Devonian lavas and tuffs flanking Glen Coe—which occupied an elliptical area bounded by a curved fault and measuring nearly 30 square miles—had been let down more than a thousand feet into the midst of Highland schists. This 'cauldron subsidence' was inferred to be sub-aerial and to have been formed, in part at least, at the time of the volcanic activity; it was proved to be partly contemporaneous with the broken ring of intrusive igneous rocks associated with the curved fault. Shortly after the announcement of this discovery came that of Bailey's interpretation of the Highland schists in the neighbourhood of Fort William and Ballachulish. He claimed them to have been folded in a recumbent manner and accompanied by fold faults or slides which in places had cut out great thicknesses of rock. But R. G. Carruthers (who died on the day of

Bailey's cremation) in 1913 disputed the correlation made by Bailey of some of the units in the succession. Bailey was unconvinced of his errors until 1930 when others had pointed out that current bedding provided incontrovertible evidence of the original order of stratal deposition; he then corrected various details in his interpretation of the tectonic pattern, but the concept of recumbent folding has survived. Bailey's final reassessment of this work appeared in his second edition of the *Geology of Ben Nevis and Glen Coe* (1960).

Further distinguished work was undertaken by Bailey and his colleagues in the Inner Hebrides, where they elucidated the complicated history of the Tertiary volcanic centre in Mull and the various stages of the igneous activity there. Sir John Flett in 1937 stated this to be one of the most wonderful chapters of the Geology of Britain. Here in Mull, Bailey described gravitational differentiation, ring bosses, pillow lavas, crater lakes and ring dykes. The last name took its currency from Bailey's first usage in 1915. After his return from the First World War in 1919, Bailey was placed in charge of the Survey's West Highland field unit. He took over supervision of the team-work in other parts of Mull, Ardnamurchan and Coll, and he brought to publication the one-inch geological map of Mull and the two classical memoirs thereon (1924, 1925). During this period he re-examined the Cretaceous sands on the west side of Loch Aline and from their very high silica content he deduced them to be the desert shore sands of the Chalk sea. The  $\text{Fe}_2\text{O}_3$  impurity being only 0.02 per cent, the deposit was later developed as a source of optical glass sand, and between 1940 and the autumn of 1948 a quarter of a million tons were shipped from a mine excavated in it.

While at Glasgow, Bailey continued his investigation of the manifestations of Earth movement and, inspired by his studies with R. M. Field and L. W. Collet on the effects of Palaeozoic submarine land-slippling near Quebec, he wrote with Dr. John Weir on faulting in Kimmeridge times which had produced spectacular effects off the coast of East Sutherland. He also wrote his book, *Tectonic Essays: mainly Alpine* (1937).

His plans for directing the Geological Survey were thwarted by the needs of the War years. The activities of the staff were then diverted to appraising, for concentrated utilization in the War effort, the country's natural mineral resources. These included coal, iron-ore, barytes, fluor spar, tungsten-ore, potash-feldspar, water and oil. The Survey's headquarters were partly occupied by another Government department, and as a spare-time activity Bailey was appointed in 1940 lieutenant commanding the Geological Survey and London Civil Defence Region section of the Home Guard, which duties he undertook with enthusiasm until 1942. In 1943 he had a short spell in Malta to advise on water resources there. He retired in 1945. He continued geological work after retirement, at first in Iran, and then in Turkey, the latter with Prof. W. J. McCallien. In recent years with the last-named he studied a problem in Apennine tectonic geology.

His keen walking and mountaineering activities led him to support the Scottish Youth Hostels' Association, of which he was successively Glasgow District chairman, vice-president and honorary president. He much enjoyed writing biographies of geologists. His book on Charles Lyell was published in 1962, and before he died he had prepared a study on James Hutton.

Bailey was elected to the fellowship of the Royal Society in 1930 and he received a Royal Medal in 1943. From the Geological Society of London he received the Bigsby, Murchison and Wollaston Medals. Honorary

doctorates were awarded to him by the Universities of Belfast, Birmingham, Cambridge, Edinburgh, Glasgow and Harvard.

His married life with Alice Meason started in 1914 and was ended by her death in 1956; they were devoted to each other and had a son and a daughter. In December 1962 he married Miss Mary Young, who survives him.

C. J. STUBBLEFIELD

### Dr. C. M. Merrihue

DR. CRAIG M. MERRIHUE, physicist of the Smithsonian Astrophysical Observatory and associate of Harvard University, Cambridge, Massachusetts, died in a mountain-climbing accident on March 14, 1965.

Born in Schenectady, New York, on July 8, 1933, he was awarded the B.A. degree from Harvard University in 1956, and the Ph.D. from the University of California at Berkeley in 1964. He lived in Cambridge, Massachusetts, with his wife Sandra and their son Jeffrey.

Dr. Merrihue's professional accomplishments were, of course, mainly ahead of him. However, in his short career he demonstrated an unusual combination of theoretical skills and experimental aptitude, and made important contributions to science. His first published work placed upper limits on a  $\beta$ -branch in  $^{124}\text{I}$  by examining with a mass spectrometer the xenon with deutron-irradiated tellurium. Other investigations helped determine the isotopic composition of the rare gases in several meteorites, with particular emphasis on xenon anomalies, which were being intensively studied in the laboratory of Prof. J. H. Reynolds at Berkeley, California.

One of Dr. Merrihue's most important discoveries was the finding of unusually large anomalies in xenon isotope composition in chondrules of the Bruderheim meteorite. These chondrules displayed the highest  $^{136}\text{Xe}/^{138}\text{Xe}$  of any meteoritic material yet examined, and supported the suggestion of a very primitive origin for chondrules. For this work he received the first Nünninger Meteorite Award.

His analysis showed large differences in the amounts of both anomalous  $^{136}\text{Xe}$  and total xenon in different minerals of the matrix. These matrix xenon variations were non-

linearly correlated, and distinctly different from the xenon observed in all other chondrules investigated. He used these observations as further evidence for the *in situ* origin of excess  $^{136}\text{Xe}$ . As a result of these investigations, Bruderheim is at present the only meteorite for which we have such complete xenon and krypton data on separated minerals.

In conjunction with the Bruderheim measurements, Merrihue embarked on a series of computer calculations. These included Monte Carlo calculations of the production of xenon isotopes by possible early solar-system irradiations of meteoritic target elements, and investigations of rare-gas diffusion. He also noted the great power of combining neutron activation of meteorites with mass spectrometry of the rare gases as a tool for determining the chemical abundance, and in favourable cases the isotopic abundance, of a list of elements. This technique also provides an elegant method of potassium-argon dating of small samples. He also made rare-gas measurements of a magnetic separate from a Pacific red-clay deep-sea sediment, and found isotopic anomalies suggesting the possible presence of extraterrestrial dust in this material. These applications of mass spectrometry to problems of meteorites and cosmic dust and of the history of the solar system were imaginative and fruitful and provided many important new data.

Merrihue was a quiet, modest, unassuming man with intense enthusiasm for life. He was deeply involved in the public problems of his time, taking an active interest in conservation, civil liberties, and political issues. He was concerned alike for the individual and for society.

A skilful mountain climber, he had led an expedition to the Andes, had climbed in British Columbia and in the Karakoram in Pakistan, and was planning an expedition to the Hindu Kush in Afghanistan. While he and Daniel Doody, a member of the American Everest Expedition, were climbing on the side of Mt. Washington, they both fell and were killed.

Because of his theoretical interests and practical skills as a scientist, and because of his experience as a mountain climber, Dr. Merrihue was a conspicuous candidate for the position of scientist on America's first manned expedition to the Moon.

## NEWS and VIEWS

Chief of the C.S.I.R.O. Division of Biochemistry and General Nutrition: Dr. H. R. Marston, F.R.S.

IN August 1965, Dr. Hedley R. Marston relinquishes the position of chief of the C.S.I.R.O. Division of Biochemistry and General Nutrition, Adelaide, having reached the age of retirement. When the Division was established in 1944 he was appointed as its first chief. He had been associated with the division of animal nutrition since its formation in 1927. It has always been Marston's firmly expressed belief that the only safe road to practical advance in applied science is through the understanding of the underlying natural phenomena, and his own research fully confirms this. His earlier work included investigations of the thermo-dynamics of ruminant nutrition, and fundamental studies of the protein requirements for wool production. His name, however, is most widely known for his work on the nutritional importance of trace elements, in particular of cobalt, copper and zinc. He and his colleagues were responsible not only for showing that soil deficiencies of copper and zinc prevented the growth of many food crops and that deficiencies of either cobalt or copper may prove fatal to sheep, but also for tracing an ultimate role of cobalt to its incorporation, after conversion to vitamin B<sub>12</sub>, by micro-organisms of the rumen, into methyl-

malonyl co-isomerase. It must be a lasting satisfaction to him that his work has brought prosperity to many parts of the world, and not least to the region in which he was born and lived, for his birth-place was Bordertown, on the edge of what was then known as the 'ninety mile desert'. Marston, like other men of high mental stature, is never slow to acknowledge his debt to others. In conversation, he mentions many names with affection, perhaps most frequently those of C. J. Martin, his former chief, Sir David Rivett, who was the architect of the Australian C.S.I.R., and Sir Frederick Gowland Hopkins, in whose laboratory he worked in 1936-37.

Zoology at the University of Cambridge:

Prof. T. Wels-Fogh

DR. TORBEN WELS-FOGH, who has been elected to succeed Prof. C. F. A. Pantin (*Nature*, 183, 506; 1959) as professor of zoology in the University of Cambridge from October 1966, was born in Aarhus, Denmark, on March 25, 1922. He studied zoology in the University of Copenhagen and already as a student of twenty-two he showed his extraordinary scientific talent by winning a gold medal for a zoological prize essay on soil ecology. In 1947 he took his degree as *Magister scientiarum* in zoology and became assistant in research to the retired Prof. August

Krogh, who in his private laboratory had taken up an investigation of the flight of insects. The participation in these studies led Weis-Fogh into a number of interesting problems ranging from the mechanical problems of flight, muscle- and nerve-physiology to metabolism and chemical investigations on the properties of mechanical components in the structure of the flying mechanisms. After Krogh's death in 1949, Weis-Fogh acted as head of Krogh's private laboratory until 1953 (supported by the Anti-Locust Research Centre, London). During 1953-54 he joined Prof. F. Buchthal at the Neurophysiological Institute as associate lecturer in the University of Copenhagen. In 1954 his connexion with the University of Cambridge began with a visit to the Department of Zoology as Fellow of the Rockefeller Foundation. From 1956 he was Balfour Student of the University of Cambridge and member of Trinity College, but in 1958 he was asked to return to Copenhagen to be professor in zoophysiology and head of the Zoophysiological Laboratory B of the University of Copenhagen. In 1961 he acted as Prather lecturer in biology in Harvard University. He is a Fellow of the Royal Danish Academy of Sciences and Letters and of the Danish Academy of Technical Sciences.

The professorship in Copenhagen was a research professorship with no formal teaching duties, and the work of Weis-Fogh and his collaborators in the years since 1959 has resulted in a series of important papers on many subjects, among which may be mentioned the co-ordination of motor activity in flight, diffusion problems, tracheal respiration and a number of papers on a peculiar rubber-like protein, resilin, found in the locust cuticle. Though Weis-Fogh considers research his main activity, his general interest in the development of Danish science forced him to spend time and energy on organization problems. He has been in the forefront of the fight for re-organization of the University of Copenhagen and of the structure of Danish science. He will be missed in Denmark not only as an inspiring scientist but also as an organizer and teacher of advanced students. While regretting his departure from Denmark, his colleagues wish him success in his new position and hope that it will lead to a strengthening of the ties between British and Danish science.

#### Mechanical Engineering in the Massachusetts Institute of Technology : Prof. A. H. Shapiro

PROF. ASCHER H. SHAPIRO, well known for his work on fluid dynamics and a leader in revising and improving engineering education in the United States, has been appointed head of the Department of Mechanical Engineering at the Massachusetts Institute of Technology. He has been on the teaching staff of the Institute for twenty-five years. He succeeds Dr. H. Guyford Stever, who has been appointed president of the Carnegie Institute of Technology in Pittsburgh. Emeritus Prof. O. Richard Soderberg has been acting head of the Department pending the appointment of a permanent successor to Prof. Stever. Prof. Stever also was head of the Institute's Department of Naval Architecture and Marine Engineering. Prof. Soderberg has also been acting head of this Department on an interim basis and he will continue in this capacity until a successor to Dr. Stever is appointed. Prof. Shapiro is at present chairman of the Faculty of the Massachusetts Institute of Technology. Prof. Shapiro has received international recognition in recent years for his development of motion-picture films as a significant component of engineering education. He was founder and first chairman of the National Committee for Fluid Mechanics Films, which, under sponsorship of the U.S. National Science Foundation, is producing films which have already been so influential as to have inspired similar efforts in other areas of engineering education. He is at present chairman of the Committee on Educational Films of the Commission on Engineering Education.

His research and professional activities for industry and Government have been principally related to the engineering problems of power production and propulsion engines. During the Second World War, he directed for the Navy Bureau of Ordnance a laboratory charged with the development of torpedo engines. He was a member of the Lexington Project which in 1948 evaluated the technical feasibility of nuclear-powered aircraft, in the course of which he invented a new form of nuclear-aircraft-propulsion system. In 1953, he directed "Project Dynamo", which evaluated for the Atomic Energy Commission the technology and economics of nuclear power for civilian use and which predicted the competitive economic position which nuclear power is assuming to-day. In the area of Government service, he has been a member of advisory groups to the National Advisory Committee for Aeronautics, and to the Office of the Secretary of Defence, and he is at present a member of the Scientific Advisory Board of the U.S. Air Force.

#### Physics in the University of Saskatchewan :

Prof. L. Katz

PROF. LEON KATZ, professor of physics and director of the Linear Electron Accelerator Laboratory at the University of Saskatchewan, Saskatoon, has been appointed head of the Physics Department at that University. He succeeds Dr. R. N. H. Haslam, who was appointed dean of arts and science at the University in 1964, and who is resigning the headship in physics to devote more time to his duties as dean. Dr. Katz has been with the University of Saskatchewan since 1946. He is best known for the part he played in establishing on the Saskatoon campus the recently opened linear accelerator laboratory, which is Canada's newest and largest laboratory for nuclear research. Besides extensive research in the field of nuclear physics, Dr. Katz has also conducted investigations in thermodynamics, micro-wave spectroscopy, and the ratio of specific heats of gases. Before joining the University of Saskatchewan, Dr. Katz was an engineer in the Electronics and Electro-Mechanical Division of the Westinghouse Electric Manufacturing Co., Pittsburgh. Dr. Katz was born in Poland, but when he was quite young his family emigrated to Canada and he attended public and high school in Toronto. He gained B.S. and M.S. degrees from Queen's University, Kingston, and was awarded a Ph.D. by the California Institute of Technology. Dr. Katz is a Fellow of the Royal Society of Canada, a Fellow of the American Physical Society, a member and past president of the Canadian Association of Physicists, and a member of the Physical Society (Great Britain). He was chairman of the Canadian Association of Physicists Committee set up to acquire a high-energy machine for Canada.

#### Marine Nuclear Propulsion

In a written answer in the House of Commons on July 7, Mr. F. Cousins, the Minister of Technology, stated that at June 30 about 95 qualified scientists and engineers were engaged on research and development on marine nuclear propulsion within his Department, including the Atomic Energy Authority and the Ship Research Association. This figure compared with 140 in 1964, 180 in 1963, 95 in 1962, 55 in 1961 and 30 in 1960. The cost of research and development in this field had been as follows: £0.2 million in 1961-62; £1.4 million in 1962-63; £2.2 million in 1963-64; £2.0 million in 1964-65; £0.3 million in the first quarter of 1965-66.

#### Grants to University Students

In a written answer in the House of Commons on July 2, Mr. A. Croxall, the Secretary of State for Education and Science, stated that total expenditure on grants to university students in England and Wales, by the Scottish Education Department and under the

Ministry of Education State Scholarship scheme in the academic year 1961-62, was £23.1 million, or £29.3 million gross before deductions were made for assessed contributions by students and their friends. For 1962-63 the corresponding figures were £28.6 million and £35.3 million, and for 1963-64, £31.5 million and £39.3 million. The estimated expenditure by local education authorities on maintenance allowances for school pupils over compulsory school age in 1964-65 was £1.3 million.

### Medical Education

IN a statement in the House of Commons on June 29, the Prime Minister said that the Queen had approved the recommendation that a Royal Commission on Medical Education should be appointed with the following terms of reference: To review medical education, undergraduate and postgraduate, in Great Britain and in the light of national needs and resources, including technical assistance overseas, to advise the Government on what principles, future development, including its planning and co-ordination, should be based. In particular, in the light of these principles, and having regard to the statutory functions of the General Medical Council and the current review by that Council of recent changes in the undergraduate curriculum, to consider what changes might be needed in the pattern, number, nature or location of the institutions providing medical education or in its general content and to report.

The Prime Minister said that the Queen had approved the appointment of Lord Todd as chairman, and the names of the other members would be announced later. The appointment of this Commission marked the importance which the Government attached to a fundamental review of the whole structure of medical education, its organization, content, and claims on resources. Meanwhile, the Government was reviewing the immediate measures which could be taken in the field of medical manpower, and the appointment of this Commission would not delay any action which needed to be taken as a result of this review. In reply to questions, Mr. Wilson added that while no decision as to new medical schools could be taken before the Royal Commission had reported, action could, of course, be taken on the immediate measures required without waiting for the Commission's report.

Following a similar Statement in the House of Lords on the same day, Lord Taylor added that Nottingham had been approved by the previous Government as the site of a new medical school, and an academic plan for that medical school had just been published; discussions would now proceed between the University there and the University Grants Commission. He also confirmed that although further medical schools could not immediately be created, it was not clear whether the best way of meeting the immediate need was by establishing more medical schools or by increasing the intake of existing ones. He emphasized that the Government was carrying out a review now, without waiting for the Commission to report, on the immediate measures that could be taken in this field to increase the supply of medical students and doctors.

### Overseas Development and Service Bill

IN moving the second reading of the Overseas Development and Service Bill in the House of Lords on July 1, Lord Taylor, the Parliamentary Under-Secretary of State for Commonwealth Relations and the Colonies, said that the Bill extended and developed the provisions of the Colonial Development and Welfare Acts of 1959 and 1963 and the Overseas Service Act of 1961, being concerned both with capital development and technical assistance. Under Clause 1, the Bill raised the ceiling on the amount which could be spent on Colonial development and welfare, and advanced the date by which the money could be spent for a further four years. Since its provisions overlap

with the existing Act of 1963, it provided for five years in all, from April 1, 1965, to March 31, 1970. As much of the money provided under the previous Act remained unspent, the total amount available in the new period would be £95 million in grants and £40 million in loans for dependent territories only, compared with £68.5 million for grants and £32 million for loans in three years only, under the previous Acts. The population of the dependent territories, however, had fallen from 18.75 million to 5.5 million as territories became independent. Under the previous Act the ratio of grants to loans was slightly more than 2:1, and this has now been increased so that 70 per cent of the aid available in the Bill would be by grants. These were considered to be more important than loans, as they do not put a further burden on the developing territories. Such sums would only be available for individual schemes within Colonial Development Plans, and under the main Act such Plans had to be approved by the Colonial Secretary, who consulted fully with the Minister for Overseas Development. Grants were available only towards the execution of plans which had first been approved; all the advisory services of the Ministry of Overseas Development could be brought to bear on the development problems of these territories.

Under Clause 2 the Overseas Service Act, 1961, was repealed and replaced, and the present Overseas Service Air Scheme was extended to cover people who were performing public or social services in overseas territories outside the Civil Services. Forty-one agreements have been signed under this Scheme, and at its peak more than 15,000 officers had been designated. More than 10,000 officers were still in posts under the Scheme in both independent and remaining dependent countries, of whom about 5,000 were members of the Overseas Civil Service, the rest being designated contract officers. Emphasis had been placed on maintaining, through a large number of short-term contracts, a considerable body of officers in the field to help overseas Governments to attain independence and to develop that independence as effectively as possible: the need for this help had not been reduced by independence. Although about 1,800 appointments were made under the Scheme in 1964, the vacancies outstanding at the end of the year exceeded the appointments made. With one major exception, the Government had not yet chosen the bodies to whom help (under the Scheme) should be offered, but it had begun a process of consultation so as to list a large number of bodies who might be eligible and then to assign some order of priority in the offers of help which could be made. It was estimated that the cost of this extension would rise to a maximum of about £1.5 million a year; the whole Scheme is at present costing the Government between £15 and £16 million a year.

### Mount John University Observatory, New Zealand

THE University of Pennsylvania, United States, and the University of Canterbury, New Zealand, formally opened the Mount John University Observatory, New Zealand, on July 10. The Observatory is the result of a joint project which began in 1961, and is situated at 3,500 ft. on the top of Mount John near Lake Tekapo in South Canterbury. It was, in fact, in limited operation before the official opening, and a 16-in. reflector telescope and an 8-in. refractor telescope lent by F. M. Bateson (a New Zealand research associate of the University of Pennsylvania) were operative. In use also was a 10.5-m. astrophotographic camera, which is utilized for taking pictures of large areas of the sky, and which was originally installed in the University of Pennsylvania's old Cook Observatory at Wynnwood. Pennsylvania has sent a renovated and rebuilt 18-in. refractor telescope which was originally installed in the University's old Flower Observatory, Upper Darby. This telescope is being stored until a structure can be built to house it. The University also

has plans to send a 39-in. reflector telescope to the New Zealand site. The University of Pennsylvania has entered into an informal working relationship with the General Electric Company. The General Electric Space Sciences Laboratory plans to collaborate with Pennsylvania and Canterbury at the Mount John Observatory on research into the atmosphere and surface features of other planets. Besides helping with the reconditioning of the 18-in. refractor telescope, the Company has provided a digitized photometer.

The original agreement between Pennsylvania and Canterbury has been renewed for a 10-year period dating from April 20, 1965, and will be renewable for subsequent 10-year periods. Pennsylvania will support a full-time astronomer at the facility to make observations and train students. He will be the astronomer in charge. Canterbury will provide two people for technical support. Students from both universities will train at the Mount John Observatory. At least one assistantship will be made available annually for a Canterbury graduate enrolled in Pennsylvania's Graduate School of Arts and Sciences. Pennsylvania has made arrangements to send two graduate students to the observatory during the 1965-66 academic year, one in September and one in January. A technician and a weather observer are already on duty at the site.

#### Benjamin Gompertz, F.R.S. (1779-1865)

JULY 14, 1965, marked the centenary of the death of the distinguished mathematician Benjamin Gompertz, who became one of the leading actuaries of his day, being the first actuary of the Alliance Assurance Company from its foundation in 1824 on the initiative of Nathan M. Rothschild and Sir Moses Montefiore, until his retirement in 1847. Gompertz married the sister of Sir Moses in 1810. Although Gompertz retired a year before the formation of the Institute of Actuaries, he was made an honorary member in recognition of his distinguished work in the actuarial field, and particularly his papers on life contingencies which were submitted to the Royal Society in 1820 and 1825. The Council of the Institute of Actuaries, to commemorate the centenary of his death, is to publish a commemorative article in its *Journal* (91, Part II, available after September 1965) and has hung a photographic reproduction of a portrait of Gompertz at Staple Inn Hall.

#### The American Philosophical Society

*Year Book 1964* of the American Philosophical Society as usual includes lists of officers and committees, members, lectures, meetings, biographical memoirs and, in the report of the Committee on Publications, a list of publications during the year (Pp. 780. Philadelphia: American Philosophical Society, 1965). Besides the Charter and Laws of the Society, the *Year Book* includes Dr. E. G. Conklin's brief history of the Society, and reports from the Committees on the library and on research. From the Pension Fund the latter Committee approved 292 grants totalling 273,600 dollars during the year; from the Johnson Fund, 56 grants amounting to 53,900 dollars; and from the Daland Fund for Research in Clinical Medicine, four fellowships, three of 8,000 dollars and one of 7,000 dollars. Two grants, one of 1,000 dollars and one of 900 dollars, were made from the Michaux Fund. Lists of recipients of grants and notes on the investigations in progress are included in the Committee's report.

#### Museums Journal

THE *Museums Journal* for June (65, No. 1; 1965) includes an informative article on the Public Libraries and Museums Act, 1964, so far as it concerns local authority museums. All previous Acts on museums are repealed, and Mr. John Edwards summarizes the Act in non-legal language. Although local authority museums

now have the power to charge for admission, it is doubtful whether many will avail themselves of this clause in the Act. Mr. E. L. Seyd gives a full and illustrated description of the Cannon Aquarium and Vivarium at the Manchester Museum. This has been provided in a typical exhibition gallery, and apart from its educational function has been much appreciated by the general public. Mr. Kenneth Hudson, in an article on "The Taming of Industrial Archaeology", feels that we must recognize that many individuals are "historical defectives", in the same way as we recognize colour-blindness. It is the present task of those interested to sell the ideas of the preservation of early industrial monuments and activities to the public. The issue also includes the annual report of the Council of the Museums Association for the year ended March 31, 1965.

#### The National Lending Library

THE National Lending Library for Science and Technology, which is trying to make its collection of recent conference proceedings as comprehensive as possible, has issued an *Index of Conference Proceedings Received* during 1964, together with a few received earlier (Pp. lv+60. Walton, Boston Spa: National Lending Library for Science and Technology, 1965). The *Index* is in two parts: the first part lists the title of the conference proceedings, giving place and date of conference, as well as conference number; the second lists subjects alphabetically by key words taken from the titles of the conference proceedings. Some 1,400 conferences are listed, and it is proposed to publish further indexes quarterly.

#### Fire Research Literature

THE Joint Fire Research Organization of the Department of Scientific and Industrial Research and Fire Offices' Committee has issued a list of recent reports, etc., published during 1959-August 1964 (Pp. 16. London: Department of Scientific and Industrial Research and Fire Offices' Committee Joint Fire Research Organization, 1964). The list covers, first, Stationary Office Publications, obtainable direct from H.M.S.O., and, secondly, other publications, obtainable free of charge from the Director, Joint Fire Research Organization, Boreham Wood, Hertfordshire. The latter are classified under: occurrence of fire; fire hazards; initiation and development of combustion; fire resistance; fire-fighting; and general, including works of reference.

#### Biological Characterization of Human Tumours

DURING May 27-29 a symposium was held on "The Biological Characterization of Human Tumours" under the auspices of the European Committee for Human Tumour Investigations, which was formed in 1961 in London during a meeting at the Chester Beatty Research Institute (see *Brit. Med. J.*, i, 1752; 1961; and *Nature*, 189, 627; 1961). Most of the contributions will be published in the new *European Journal of Cancer*, including those dealing with the main problems of "Long Term Cultures of Organized Human Tumours" (Prof. Etienne Wolff), "Enzymology of Human Tumours" (Dr. G. E. Boxer), "Histochemistry and Tumour Characterization" (Dr. R. J. G. Willighagen), "Evidence of Immunologic Reaction to Autochthonous Cancer in Man" (Dr. C. M. Southam), and "Viruses and Human Tumours" (Dr. R. J. C. Harris). In addition, a number of short papers on various aspects were presented, and the common difficulties arising out of work with human samples were thoroughly debated. A subsequent meeting of the European Committee discussed the formation and extension of study groups and working plans for the future.

#### C.S.I.R.O. Publications

THE Commonwealth Scientific and Industrial Research Organization, Australia, has issued a list of publications

of the Organization and of its predecessors to December 31, 1964 (*List of Publications*. Pp. 58. East Melbourne: Commonwealth Scientific and Industrial Research Organization, 1965). The *List* includes details of handbooks and monographs, journals, bulletins, pamphlets, circulars, annual reports, divisional publications and publications in the *Land Research Series* and soil publications. A subject index is provided.

#### Federation of European Biochemical Societies

THE Federation of European Biochemical Societies has created the post of secretary-general and has appointed Prof. W. J. Whelan to this office. The chairman of the Federation for 1965-66 is Prof. K. Zakrzewski. The Federation, founded in 1964, now unites the membership of twenty-one biochemical societies in the European area, and its activities include the arrangement of an annual international meeting, summer schools in advanced research techniques, charter travel to international congresses and, through a twice-yearly bulletin, information on biochemical meetings in Europe. The third Federation meeting will be held in Warsaw during April 4-7, 1966, and will include a symposium on "Properties and Structure of Genetic Elements" and colloquia on "Biochemistry of Blood Platelets" and "Mitochondrial Metabolism". Information on this meeting may be obtained from the Secretariat, Third Federation Meeting, Polskie Towarzystwo Biochemiczne, 16 Freta Street, Warsaw, 40, and on other Federation activities from Prof. W. J. Whelan, Royal Free Hospital School of Medicine, 8 Hunter Street, London, W.C.1.

#### University News:

##### Aberdeen

THE following appointments have been made: *Professorships*, Dr. H. F. W. Taylor (newly created third chair of chemistry); Dr. K. Walton (newly created second chair of geography); Dr. J. R. Symons (newly created second chair of psychology); Dr. J. R. Mallard (newly created chair of medical physics); *Senior Lectureships*, Dr. J. D. Lambert and Dr. D. R. Wallace (mathematics); *Lectureships*, Dr. R. Shilton, Dr. L. S. D. Glaeser and Dr. J. A. Duffy (chemistry); M. S. Philip (forestry); *Research Fellowship*, A. L. Fallas (chemistry).

##### Belfast

DR. J. C. BROWN has been appointed to the chair of computer science. The following lecturers have been appointed: Dr. J. J. Rooney (physical chemistry); Dr. O. M. White (physics); R. Jennings, J. D. Williams, A. S. Bahrani and W. J. Skelton (mechanical engineering); A. E. Hadden, D. M. Luke, H. R. Marten and K. H. Edwards (electrical engineering).

##### Bristol

THE following appointments have been made: *Readerships*, Dr. A. Kellar (physics); Dr. J. F. Nye (experimental physics); Dr. A. F. W. Hughes (zoology); Dr. J. B. Chappell (biochemistry); Dr. R. T. Severn (civil engineering); *Lectureships*, Dr. N. W. Ashcroft (theoretical physics); Dr. M. Green (organic chemistry); Dr. R. Parikh (pure mathematics); R. G. Morgan (civil engineering).

##### Cambridge

MRS. A. GREGORY has been elected to the Perrott-Warrick studentship in psychical research at Trinity College.

##### Edinburgh

THE following lecturers have been appointed: Dr. F. W. Winton and Dr. J. F. Peutherer (bacteriology); Dr. S. S. Brown (clinical chemistry); Dr. D. H. Mills (forestry and natural resources); T. G. I. Hamnett (social anthropology); J. S. D. Ritchie (veterinary pathology); Dr. A. H. Maddy and Dr. A. W. Ewing (zoology).

#### London

THE following titles have been conferred: *Professor*, Dr. R. Miledi (biophysics, in respect of his post at University College); Dr. R. W. Tiffen (applied mathematics, in respect of his post at Birkbeck College); Dr. T. Estermann (mathematics, in respect of his post at University College); Dr. D. R. Wilkie (experimental physiology, in respect of his post at University College); *Reader*, Dr. T. O. Griffith and Dr. S. Zienau (physics, in respect of their posts at University College); Dr. G. Stephenson (mathematics, in respect of his post at the Imperial College of Science and Technology); Dr. M. Whitear (zoology, in respect of her post at University College); Dr. N. C. Freeman (aerodynamics, in respect of his post at the Imperial College of Science and Technology); Dr. G. G. Meynall (microbiology, in respect of his post at the Lister Institute of Preventive Medicine); Dr. J. H. Calloman, Dr. H. J. Milledge, Dr. J. H. Ridd and Dr. M. L. Tobe (chemistry, in respect of their posts at University College).

#### Sussex

DR. W. LEDERMAN, at present reader in mathematics, has been appointed professor of mathematics.

#### Announcements

DR. B. R. NIJHAWAN, director of the National Metallurgical Laboratory, Jamshedpur, India, has been elected president of the Indian Institute of Metals for the year 1965-66.

THE tenth Congrès Européen d'Hématologie will be held in Strasbourg during August 23-28. Further information can be obtained from Dr. J. Lewin, Centre de Transfusion Sanguine, 10 rue Spielmann, Strasbourg.

THE ninth international conference on the "Biochemistry of Lipids" will be held at Noordwijk during September 5-9. Further information can be obtained from Dr. J. Boldingh, Unilever Research Laboratorium, Mercatorweg 2, Vlaardingen, Holland.

THE fifth Western National Meeting of the American Geophysical Union will be held in Dallas, Texas, during September 1-3. Further information can be obtained from Dr. J. C. Harrison, Hughes Research Laboratories, 3011 Malibu Canyon Road, Malibu, California.

MEETINGS of Commission 3 and Sub-Commissions 6b and 6c of the International Institute of Refrigeration will be held in Prague during August 31-September 9. Further information can be obtained from the Secretary, International Institute of Refrigeration, 177 Boulevard Malesherbes, Paris, 17.

THE twentieth annual meeting of the Society of General Physiologists will be held at the Marine Biological Laboratory, Woods Hole, Massachusetts, during September 1-4. The programme will include a symposium on "The Specificity of Cell Surfaces". Further information can be obtained from Roger Milkman, Department of Zoology, Syracuse University, Syracuse, New York 13210.

THE seventh congress of the International Union of Game Biologists will be held in Belgrade and Ljubljana during September 5-11. The programme will include two symposia on "Chemical Products and Techniques used by Man and their Effects on Wild Life" and "Damage to Agricultural and Forest Crops caused by Game". Further information can be obtained from Prof. S. Valentinoic, Gerbiceva 60, Ljubljana.

**CORRIGENDUM.** In the article entitled "The Auckland Islands" (*Nature*, 203, 26; 1964) it was stated that the expedition referred to in the article was from the Australian Museum. It was, in fact, dispatched by the New Zealand Department of Scientific and Industrial Research and the Dominion Museum, Wellington, New Zealand.

## THE SMITHSONIAN ASTROPHYSICAL OBSERVATORY

MORE than 350 astronomers representing approximately twenty countries will participate in two space-science conferences to be held at Cambridge, Massachusetts, this summer as a part of a celebration marking the seventy-fifth anniversary of the Smithsonian Astrophysical Observatory.

The Smithsonian Observatory, in co-operation with the Harvard College Observatory, will sponsor two symposia, the first concerning meteor orbits and dust (August 9-13), and the second concerning aeronomy, or the investigation of the Earth's upper atmosphere by means of artificial satellites (August 16-20). The Smithsonian Observatory has long been a centre for research in both aeronomy and meteoritics, and specialists in these fields from around the world are expected to attend, including scientists from Iron Curtain countries.

Two popular lectures open to the public will also be delivered: the first on August 10, entitled "The Falling Stars", given by Dr. Peter Millman of the National Research Council of Canada, and the second on August 17, entitled "The Aurora Polaris in the Magnetosphere", given by Dr. Sydney Chapman of the Geophysical Institute, University of Alaska.

The Smithsonian Astrophysical Observatory, a bureau of the Smithsonian Institution, Washington, D.C., was founded in 1890 by Samuel Pierpont Langley, third secretary of the Smithsonian and a pioneer in aeronautics and early manned flight. The Observatory's early research was concerned with the relationship between solar and geophysical phenomena.

In 1955, the Observatory headquarters and research facilities were moved to the grounds of the Harvard College Observatory in Cambridge, Massachusetts. Dr. Fred L. Whipple, the well-known Harvard astronomer, was appointed director of the Observatory at that time. The emphasis of Smithsonian research was shifted to the

'space sciences' in response to growing international space programmes.

The Observatory gained widespread recognition with the launching of Russia's *Sputnik I*. The Observatory was developing a world-wide network of satellite-tracking cameras at the time, and it already had an international organization of volunteer visual observers in operation. This group of amateur observers, called "Moonwatch", provided many of the first data leading to the determination of *Sputnik's* orbit.

The Smithsonian Observatory has continued its tracking operations under a grant from the National Aeronautics and Space Administration. Optical data from its network of Baker-Nunn cameras are used to-day both in support of the federal space programme and for the research of its own scientists who use the information in investigations of the upper atmosphere, celestial mechanics, the Earth's gravitational potential, and geodesy.

Besides satellite tracking and its related research projects, more than fifty Observatory scientists are engaged in varied researches ranging from theoretical astrophysics and meteoritics to exobiology and cometary studies. As part of the National Aeronautics and Space Administration's Orbiting Observatory programme, Smithsonian scientists are also preparing instrumentation for future satellite and balloon flights.

The Smithsonian Observatory's data-gathering facilities include the world-wide network of twelve Baker-Nunn satellite-tracking cameras, an unmanned network of sixteen camera stations in the mid-western United States for photographing bright meteors, a system of radar and optical tracking stations on the Virginia coast for observing simulated or 'man-made meteors', and, with the Harvard College Observatory, a radar system at Havana, Illinois, for the detection of ionized trails from micro-meteorites.

## LACK OF HOMOLOGY IN THE OSCILLATIONS OF NEUTRON STARS

By DR. SACHIKO TSURUTA

Smithsonian Institution Astrophysical Observatory, Cambridge, Massachusetts

THE examination of highly condensed matter is important in itself as a fundamental problem in physics. Its importance has recently been increased because of a possibility that the presence of dense stellar matter in the form of a neutron star may be responsible for some of the celestial X-ray sources now known to exist. Oppenheimer and Volkoff<sup>1</sup> discussed the dynamical stability of neutron stars by calculating free energies. A variational principle was used by Misner and Zapolaky<sup>2</sup> for such investigations. Both approaches were used by Wheeler *et al.*<sup>3-5</sup>, who extended the problem to more general cases. This article presents some results of recent calculations which show how various possible forms of the nuclear potential are related to the general stability of high-density objects.

For stars to be stable they must first of all be in hydrostatic equilibrium. Models were, therefore, constructed by solving the general relativistic equations of hydrostatic equilibrium as derived by Oppenheimer and Volkoff<sup>1</sup>. In

order to estimate the dynamical stability of these models, Chandrasekhar's variational principle<sup>6-8</sup> (in its corrected form) was used. According to this principle, a sufficient condition for the occurrence of dynamical instability is that the square of the circular frequency of a radial oscillation,  $\omega^2$ , be negative. Chandrasekhar's trial function, which assumes homologous oscillations, was used.

Both the expressions for the hydrostatic equilibrium and for the dynamical stability contain the equation of state, the relation between the pressure and energy density,  $P = P(\epsilon)$ . It may be noted that the effect of nuclear forces enters our problem through this relation. When the stellar density approaches the normal nuclear density ( $3.7 \times 10^{14}$  g/cm<sup>3</sup>), the constituent particles generally experience attractive forces; but as the density increases further, repulsive forces eventually predominate. To see the effect of these forces, three different types of nuclear potential were chosen. The first, originally developed by Skyrme<sup>9</sup>, is a simple three-body effective

nuclear potential which represents fairly well many features of the more complicated many-body approach. In the present investigation, the relativistic Skyrme equation of state as given by Saakyan<sup>10</sup> was used. We shall refer to models of this kind as 'Skyrme models'. The other two potentials, denoted by  $V_\beta$  and  $V_\gamma$ , are neutron-neutron potentials derived by Levinger and Simmons<sup>11</sup>, which also are based on experimental data in the region of normal nuclear density. The case of non-interacting fermions is also considered for comparison. These are designated 'ideal' gas models. The principal differences among these potentials may be summarized as follows: For densities in the range of  $10^{12}$ – $10^{14}$  g/cm<sup>3</sup>, the Skyrme potential has the largest attractive term, and the  $V_\beta$  and  $V_\gamma$  potentials have a less attractive term, but the  $V_\gamma$  potential is somewhat more attractive than the  $V_\beta$  potential. For densities higher than about  $10^{14}$  g/cm<sup>3</sup>, the  $V_\gamma$  potential is the most repulsive, the  $V_\beta$  potential is the least repulsive, and the Skyrme potential is intermediate in its repulsive effect.

In a physically realistic equation of state, the pressure is not allowed to become indefinitely large, for two reasons. The first is the relativistic restriction that the pressure should not exceed one-third of the total energy density<sup>12</sup>. Zeldovich, however, argued that for some strong interactions this condition can be violated and that the absolute limit on pressure should be  $P \leq \epsilon$ , which implies that the velocity of sound cannot exceed the velocity of light<sup>13</sup>. (Here,  $P$  is the pressure and  $\epsilon$  is the energy density.) All nuclear equations of state considered here violate these limitations as the density is increased. Therefore, when one of these pressure saturation conditions is reached, the asymptotic equation of state  $P = \epsilon$  or  $P = \epsilon/3$  is used. The composition of pure neutrons was used throughout the work recorded here.

Generally, the mass of a degenerate star is uniquely determined for a given central density through the condition of hydrostatic equilibrium. The following general feature is common to all kinds of equations of state, independent of the nature of nuclear forces: With increasing density, the mass rises toward a principal peak, beyond which it falls and oscillates. Infinite series of such damped oscillations were predicted as the central density approaches infinity<sup>4</sup>. For each equation of state examined, about three such peaks were identified above the principal peak. When nuclear forces are not taken into account, the binding energy (the proper mass minus the gravitational mass) generally becomes negative for sufficiently high densities<sup>4–6,14</sup>. However, this negative binding in the region of high density does not occur when either the  $V_\beta$  or  $V_\gamma$  potential is applied to baryonic mixture<sup>11</sup>. The properties of the  $V_\beta$  and  $V_\gamma$  neutron star models (pure neutron configuration) are similar to the corresponding types of the baryon stars. The Skyrme models lie about halfway between  $V_\beta$  and  $V_\gamma$  models, with the principal peak at about 1.7 solar masses. The binding energy never becomes negative for the Skyrme models. The 'ideal' gas models are less massive than the  $V_\beta$  models, with the principal peak at about 0.7 solar masses. More detailed information on these models can be found in a thesis<sup>14</sup>.

In Fig. 1 the square of the circular frequency,  $\omega^2$ , is plotted as a function of the central energy density.  $\omega^2$  is expressed in relativistic units where  $c = G = 1$ , and the unit of length is  $1.86 \times 10^6$  cm. The solid curves represent the models with the pressure saturation condition  $P \leq \epsilon$ , and the dashed curves the models with the condition  $P \leq \epsilon/3$ .

The calculations exhibited in Fig. 1 of  $\omega^2$  are based on Chandrasekhar's formula, which in turn was based on a trial function in which the mode is constrained to pulsate homologously. The implicit assumption is made that such a pulsation is the fundamental model of lowest energy. If this were so, then the region of the diagram corre-

Fig. 1. Square of the circular frequency of the oscillations of a neutron star configuration based on the assumption that the fundamental mode consists of homologous radial pulsations. ---,  $P \leq \epsilon/3$ ; —,  $P \leq \epsilon$ .

sponding to  $\omega^2 > 0$  should be the stable region, and the region corresponding to  $\omega^2 < 0$  should be the region of instability.

The basic result found in these calculations is that  $\omega^2$  oscillates as a function of central density, and approaches a finite value after a number of damped oscillations as the central density goes to infinity. For some cases three such oscillations are recognizable in Fig. 1. This is a feature common to other stellar parameters, such as mass and radius. This property is found to be independent of the type of equation of state used.

All 'ideal' gas models were found to be stable along the lower branch of the principal mass peak in the region of neutron stars. The  $\omega^2$  changes sign from positive to negative at the principal mass peak, which is also the point of greatest binding energy, as expected. The two smaller  $\omega^2$  peaks in higher density regions roughly correspond to the lower branch of the second and the third mass peaks. (These are actually the third and the fourth peaks if the white dwarf peak is included.)

Nuclear forces generally increase the value of  $\omega^2$ . The greatest contributions to the integrals which must be evaluated to obtain  $\omega^2$  occur in the outer parts of the models, where the density is relatively low. Hence it is the attractive character of nuclear forces near ordinary nuclear density which must be responsible for the increased values of  $\omega^2$ . Furthermore, it may be seen that  $\omega^2$  is more positive when the pressure saturation condition  $P \leq \epsilon/3$  is applied than when the less restrictive condition  $P \leq \epsilon$  is used.

It is evident that the failure of all values of  $\omega^2$  to become negative past the top of the principal neutron star peak violates a fundamental theorem concerning instability which is based on energy principles (theorem 17, p. 61, ref. 4). Hence it is evident that the homologous

vibration of these neutron star models cannot represent accurately the fundamental mode. The departures from homologous displacements must be much greater for models based on equations of state with nuclear force terms included. Hence more complicated trial functions must be used to test for instability of such models.

I thank Profs. A. G. W. Cameron, E. Schatzman, J. A. Wheeler, J. P. Wright and K. S. Thorne for their advice. I also thank Prof. Wheeler's group and the University of Texas for kindly making available to me a copy of a part of the manuscript of their book<sup>4</sup>. Thanks are due, also, to Profs. F. L. Whipple, C. A. Lundquist, C. Whitney and other members of the Smithsonian Astrophysical Observatory and Harvard College Observatory for their assistance.

## FORMATION OF PRECIOUS OPAL

By DR. R. K. ILER

Industrial and Biochemicals Department, E. I. du Pont de Nemours and Co., Wilmington, Delaware

**P**RECIOUS opal is distinguishable from other opaline silicas by being essentially amorphous, as shown by J. B. Jones, J. V. Sanders and E. R. Segnit<sup>1</sup>. The relation between the remarkable particulate structure and the reflected colours of precious opal has been described by J. V. Sanders<sup>2</sup>, who found that this mineral consists of regularly packed uniform spheres of amorphous silica a few tenths of a micron in diameter. From electron micrographs, Sanders concluded that the spheres must have grown in suspension by deposition of silica on to precipitated nuclei and then the spheres must have been later packed together, possibly during a filtration process.

The purpose of this article is to describe the spontaneous formation of brilliantly coloured, opal-like masses of 0.1- $\mu$  spheres of colloidal amorphous silica by aggregation from a sol and to point out the physical similarity between this and other types of similarly coloured, regular aggregates formed from inorganic and organic colloidal particles in this range of particle size.

The preparation of sols of uniform spherical particles of amorphous silica by depositing soluble silica on pre-formed nuclei has been described by M. F. Bechtold and O. E. Snyder<sup>3</sup> and the characterization of such silica has been summarized by me<sup>4</sup>.

In a 30 per cent silica sol of particles about 100 m $\mu$  in diameter, prepared by George W. Sears of this laboratory, he and I observed that after two years in quiescent storage in a 1-gallon bottle an intermediate layer showing brilliant colours in reflected light had been formed at the boundary between a dense, white, concentrated layer of colloid at the bottom and a more dilute opalescent sol remaining above.

To investigate the effect of pH, a number of 4-oz. samples of colloidal silica were withdrawn from the intermediate coloured layer, diluted with equal volumes of distilled water, adjusted with hydrochloric acid and dilute ammonia to pH values ranging from 3 to 10, and then allowed to stand in sealed glass or polyethylene bottles for another two years. In samples at pH 5 and 7, coloured layers formed within a period of 3 months; in all cases, coloured layers appeared after two years. Above pH 7, the coloured region consisted of a thin, dense intermediate layer of uniform thickness. Between pH 4 and 7 at the boundary between the concentrated and dilute regions, brilliant platelets were formed, growing upward into the supernatant liquid. These have the appearance of leaf-like or blade-like crystals, and will be referred to as 'pseudo-crystals'. These objects have been found repeatedly in silica sols of relatively uniform particle size averaging about 100 m $\mu$  in diameter; in most cases the initial silica

concentration was 5-10 per cent by weight of silica and the pH between 5 and 7. In these circumstances, the blade-shaped, coloured pseudocrystals grow to a length of 2 mm, with relatively straight sides but with the upper edges less well defined.

The colour of the pseudocrystals depends on the angle from which the light is reflected. As the bottle containing the specimen is carefully turned, new pseudocrystals of different colours come into view. It should be noted that a given pseudocrystal can be seen only by one eye at a time, since the other eye is usually not at the correct angle to see the reflected light. The colours range from brilliant yellow through yellow-green or chartreuse, orange, deep red, blue and violet. These pseudocrystals are extremely fragile and disappear if the container is jarred or slightly shaken, and are formed again only after the mixture has stood again for several months.

Unsuccessful attempts were made to produce pseudocrystals more rapidly by centrifuging sols to bring about settling in several hours, but the silica particles were pecked into white, opaque layers, leaving a translucent, almost transparent supernatant liquid. It is apparent that time is necessary for the particles to attain the required perfection of packing.

The coloured material has been isolated in dry form as chalky white masses of silica gel, still showing weak interference colours, by permitting the sol containing the coloured layer to evaporate very slowly over a period of two more years, so that the silica in the supernatant liquid is drawn down slowly on the coloured masses without disturbing them. More rapid evaporation, which obviously must involve movement of water from the bottom to the top of the mass, disturbs the structure. The slowly dried, fragile, opaque material was heated to 900° C over a period of 12 h and then slowly cooled. When the mass was impregnated with water or preferably with benzene or alcohol, the interference colours were again observable. The refractive index of the impregnating liquid had a marked effect on the reflected colours. Water with a refractive index of 1.33, as compared with 1.46 for the amorphous silica, gave a white opaque mass in which green flecks of colour could be seen. Normal butyl alcohol, refractive index 1.39, gave an almost transparent mass, showing green-blue flecks of colour in reflected light. Carbon tetrachloride, refractive index 1.46, gave a perfectly transparent mass which, however, showed slight green reflexions. An oil with a refractive index of 1.6 gave deep red reflexions, while liquids of still higher refractive index resulted in a white opaque mass with a brownish tinge.

Fig. 1. Electron micrograph of replica of polished section of close-packed spheres of colloidal silica showing reflected interference colours ( $\times c. 25,000$ )

The bulk density of solid pieces of the slowly dried silica, still showing interference colours, dried and fired to  $1,000^{\circ}\text{C}$ , was  $1.53\text{ g./c.c.}$ , corresponding to 69.6 per cent by volume of amorphous silica. This approaches the value of 72 per cent by volume, corresponding to close-packed, uniform spheres. An electron micrograph of a replica of a polished section is shown in Fig. 1.

**Formation of natural opal.** The brilliantly coloured but very fragile layers containing the pseudocrystals, viewed through the glass walls of the container, look exactly like natural precious opal. There is little doubt that the colours originate from uniform arrays of silica spheres as Sanders<sup>1</sup> has described in the case of natural opal. However, in natural precious opal the spheres are larger, and the space between them is at least partially filled with hydrated amorphous silica which serves to harden the mass. Such a cementing process probably occurred after the spheres were packed in regular array, by long-continued impregnation with soluble silica. Cementing or reinforcing of suspended aggregates of silica particles has been carried out in the laboratory to produce mechanically strong silica gels<sup>2</sup>. Impregnation of dense-packed masses of opal may have occurred by a similar but far slower process in Nature, since the solution would have to pass through the mass in order to achieve such a uniform deposition of silica.

It is probable that a critical step in the formation of natural precious opal was the creation of spheres of amorphous silica in dilute suspension and subsequent slow settling in quiescent underground pools. Since geyser waters are often supersaturated with silica, it is conceivable that in some circumstances the rate of cooling might be such that relatively large uniform particles of colloidal silica were formed. In undisturbed subterranean pools such particles might have become concentrated, and uniformly packed aggregates may have been formed just as observed in the laboratory. Once such uniform aggregates had been formed, further hardening of the structure by deposition of silica within the interstices over thousands of years could result in the type of structures described by Sanders *et al.*

There remains the question as to why uniform spherical particles of amorphous silica should become packed together in regular arrays as pseudocrystals. In the silica-water system, the changes which occur spontaneously are those which lower the area of the silica-water interface, since there is an interfacial surface energy of about  $80\text{ ergs/cm}^2$  (ref. 6). Minimum interfacial area is achieved when the surfaces of such particles are brought together, excluding the water from the areas of contact. The formation of these points of contact represents the first stages in reducing the overall silica-water interfacial surface area. Greatest reduction in interfacial area is obtained with the closest packing of spheres in which each sphere makes the greatest number of contacts with sur-

rounding spheres. In a sol containing charged particles of different sizes, particles which are either smaller or much larger than the average will not fit as perfectly into the growing uniform array of the pseudocrystals, and their inclusion is thus thermodynamically less favoured. Unless the particle colliding with the surface is held with several points of attachment, it will be repelled by the surface of the pseudocrystal which is of like charge. This is analogous to the fact that a potassium ion does not fit into the lattice of a growing crystal of sodium chloride, and is thus excluded. Thus spheres of like size tend to fit into a given growing pseudocrystal.

**Analogous systems.** Analogous aggregation of spherical particles of colloidal size to form highly coloured masses has been observed with organic materials. N. Xeros<sup>3</sup> reported that a virus in an insect caused the formation of iridescent nodules which showed brilliant colours in reflected light; when the virus is purified it is obtained as a mass showing iridescent colours. The properties of this lattice, consisting of very uniform spherical particles,  $130\text{ m}\mu$  in diameter, is further described by Williams and Smith<sup>4</sup>.

The close packing of uniform polyvinyl toluene latex particles in the size-range of  $100\text{--}1,000\text{ m}\mu$  has been described by Alfrey, Bradford, Vanderhoff and Oster<sup>5</sup>. The spontaneously formed, close-packed, crystalline array acted as a diffraction grating and particle sizes in the range of  $302\text{--}481\text{ m}\mu$  were determined by the diffraction method.

Another instance of uniformly arrayed colloidal particles showing brilliant interference colours is the formation of the so-called 'schiller layers' from colloidal hydrated iron oxide. The structure and arrangement of regularly packed masses of uniform colloidal particles of this type have been described by Watson, Cardell and Heller<sup>10</sup>.

In instances in which the spontaneous regular and uniform aggregation of charged colloidal particles occurs, it appears that at least one of the dimensions, whether the diameter of a sphere, or the width of a rod-like particle, is of the order of  $100\text{ m}\mu$  or more. Possibly this is because uniform arrays of colloidal particles are most easily recognized when the particles are in this size range and thus reflect monochromatic light of visible wave-length. However, this is also the size-range in which slow sedimentation occurs. Particles larger than about  $100\text{ m}\mu$  in diameter or thickness tend to settle so that there is a gradual increase in concentration at the bottom of the container; conditions are thus favourable for the slow segregation of particles into regular aggregates or pseudocrystals, each consisting of particles of a particular uniform size.

On the other hand, in the case of smaller particles, the Brownian motion is so strong that the rate of sedimentation is negligible and the particles do not become concentrated by settling. If the concentration is increased rapidly by centrifugation, the particles become packed randomly since there is no time for segregation and for ordered arrangements to be developed. However, if the size is extremely uniform, as with virus or certain latex particles, a relatively rapid increase in concentration can still result in the formation of a highly ordered array.

## COMPENSATING INFRA-RED SPECTROSCOPY

## THE POTASSIUM BROMIDE WEDGE TECHNIQUE

By H. McCORMICK and E. L. DEELEY

Imperial Chemical Industries, Ltd., Paints Division, Wexham Road, Slough, Buckinghamshire

AND

DR. J. TADAYON

Research and Industrial Instruments Co., 17, Stannary Street, London, S.E.11

THE compensating method of infra-red spectroscopy (sometimes called the differential or difference method) is a technique by which the spectrum of one component of a mixture may be completely eliminated from the recorded spectrum by introducing the component into the reference beam of a double-beam spectrometer. The method is also useful when, as frequently happens, information is required about a minor constituent of a mixture, where, because of overlapping of infra-red absorption bands, it is difficult or even impossible to obtain such information.

The technique is commonly used with liquid samples by compensating with known compositions in fixed path-length cells<sup>1</sup> or by using a variable path-length cell containing one constituent in the reference beam of the spectrometer and adjusting the width of the cell until this constituent is fully compensated in the sample beam<sup>2</sup>.

With insoluble or solid samples the control and variation of the solid layer or film required for compensation becomes difficult as the maximum thickness required is rarely more than 0.005 in. In an application of compensating infra-red spectroscopy to polymeric materials Willis and Miller<sup>3</sup> determined the free monomer content of

Fig. 1. A, mixture of *n*-butyl hydrogen phthalate and *p*-di-*tert.* butyl benzene; B, *n*-butyl hydrogen phthalate; C, *p*-di-*tert.* butyl benzene; D, mixture A compensated with B in the reference beam

Fig. 2. A, mixture of *p*-dibromobenzene and 1,3,5-tribromobenzene; B, 1,3,5-tribromobenzene; C, *p*-dibromobenzene; D, mixture A compensated with B in the reference beam

poly(methyl methacrylate) by using compensating wedges of monomer-free polymer in the near infra-red (1–3 $\mu$ ) where greater thicknesses may be used. Similarly, by using a thin polymer wedge Willbourn<sup>4</sup> determined the degree of branching of polyethylene and Harvey and Peters<sup>5</sup> the methyl groups in the same material.

The field of application of compensating techniques may be greatly widened, however, by using potassium bromide wedges containing one of the constituents of a mixture. By this technique compensated spectra of mixtures may easily be obtained in the 'finger-print' region of the spectrum.

The extension of the usual technique of producing a parallel-faced disk of potassium bromide by pressure *in vacuo* to producing a rectangular wedge proved difficult but was solved satisfactorily by one of us (J. T.), and diagrams of a suitable die (patent applied for) in plan and sections are shown in Fig. 5. This die under a pressure of 25–26 tons makes wedges of potassium bromide 24 mm  $\times$  13 mm in size with a slope of one in twelve. (A wedge 13 mm  $\times$  13 mm  $\times$  2 mm taper requires 12 tons pressure.) No doubt it could also be used with other suitable infra-red transparent materials.

The method of preparing a wedge is to grind together by hand in an agate mortar approximately 1.5 g of spectroscopic grade potassium bromide with a suitable weight of the compensating constituent of a mixture (0.2–2 mg) using, if necessary, a small amount of a volatile solvent. The mixture is then ground again in a vibrating

Fig. 3. A, polyvinyl acetate plasticized with dibutyl phthalate; B, polyvinyl acetate; C, dibutyl phthalate; D, composition A, compensated with B in the reference beam.

Fig. 4. A, 46 per cent linseed oil-modified glycerol alkyl resin; B, 63 per cent linseed oil-modified glycerol alkyl resin; C, bodied linseed oil; D, composition B compensated with A in the reference beam. This compensated spectrum shows the excess of bodied linseed oil C in B. The negative absorption at 5.9 μ is due to the higher acid value of A.

Fig. 5. Diagram of infra-red wedge die: a, plan (ram removed); b, section through AB; c, section through CD.

mill, thoroughly dried and pressed *in vacuo*. The resulting wedge will last indefinitely if stored in a desiccator.

In order to compensate for the optical displacement of the image of the reference beam in the spectrometer, a second wedge of the same size made from pure potassium bromide is clipped to the face of the constituent-containing wedge so that a rectangular block is formed. The combined wedges are then placed in a holder provided with a micrometer adjustment which allows the thickness of the constituent-containing wedge in the reference beam to be varied. With this holder placed in the reference beam of the spectrometer, the transmission is adjusted with a comb to approximately 80 per cent at a frequency at which the major constituent is transparent. The sample is prepared in the form of a potassium bromide disk and placed in the sample beam; the instrument is run and the major absorptions of the known constituent balanced out by adjusting the micrometer screw. With the instrument thus adjusted the complete spectrum of the mixture less that of the known constituent may be obtained.

Over-compensation may result in a spectrum containing negative bands which would be difficult to interpret. It may be advisable, therefore, to undercompensate and leave weak, identifiable bands of the major constituent.

If the known constituent preponderates in the mixture, the concentration of the sample in the disk must be increased. A point is reached, however, beyond which the available energy decreases very rapidly and the instrument response becomes sluggish, since speed of response is a function of the transmitted energy. In such cases it is advisable to reduce the scanning speed or to reach a compromise between the instrument response and the intensity of the absorptions of the minor constituent. The optimum operating conditions are when the absorption of the mixture at a common wave-length is 60–70 per cent.

The preparation of disks of different sample concentrations is time-consuming. A wedge containing the sample can advantageously be used in the sample beam in a holder similar to that in the reference beam, thus providing a wide choice of path-lengths.

Such a wedge, indeed, can be used in non-compensating techniques in order to arrive quickly at a suitable concentration of sample.

Infra-red spectra obtained by this technique are shown in Figs. 1–4. They were obtained with a Grubb Parsons G.S.2A instrument run at a speed of  $1\mu/2$  min, which is half the normal speed.

## EFFECT OF COLLOIDAL PARTICULATES ON FOAM FRACTIONATION

By PROF. ROBERT B. GRIEVES and DIBAKAR BHATTACHARYYA

Illinois Institute of Technology, Chicago

CHEMISTS, biologists and engineers have used foam fractionation to remove from aqueous solution soluble organic compounds and also inorganic cations and anions by complex formation with surface-active agents<sup>1,2</sup>. The process utilizes the surface-active properties of soluble organics to provide accumulation at the air-aqueous solution interfaces associated with bubbles. Froth flotation, which in contrast involves a three-phase system including a solid phase, has been applied to numerous commercial processes including ore purification and industrial waste treatment<sup>3,4</sup>. This process relies on the flotation of particles by aeration and bubble attachment which have been made selectively oleophilic by the addition of a surface-active collector. Most froth flotation processes involve coarse suspensions, and little attention has been paid to colloidal-size particulates.

For the removal of soluble organics by foam fractionation, limitations may arise owing to low surface activities of the organics and to the low concentrations which may be involved. For such solutions, the addition of colloidal particulates may provide more efficient separations through the replacement of the foam fractionation mechanism by a froth flotation mechanism. The aeration of a combined process stream containing both soluble organics and particulates may produce the effective removal of both constituents. Investigations have been made of the foam fractionation-flotation of systems containing stannic oxide<sup>5</sup> and silver iodide<sup>6</sup> together with cationic surface-active agents. The objective of this investigation is the quantitative determination of the effect of positively charged ferric oxide particulates (or polynuclear species) on the separation of an anionic surfactant, dodecyl sodium sulphate (DSS), from aqueous solution. The influences of pH, feed surfactant concentration, and feed particulate concentration are established. A brief discussion of the stannic oxide-CTAB system is included.

The hydrolysis of ferric chloride in vigorously boiling distilled water provided a positively charged ferric oxide sol<sup>7</sup>. The sol contained 292 mg/l. trivalent iron (Fe<sup>3+</sup>) as measured by the standard phenanthroline method<sup>8</sup>. Dilutions were made for the foaming experiments, and the pH was adjusted from the range 2.0–3.1 to the required values with sodium carbonate solution. The experimental apparatus was similar to that used for the ion flotation of dichromate<sup>9</sup>. The foam column was 130 cm high and 1.0 cm in diameter; nitrogen gas was saturated with water, passed through a calibrated rotameter, and diffused through a 36 $\mu$ , porous metal dispersion disk.

In each experiment 2,000 ml. of feed sol, including varying concentrations of dodecyl sodium sulphate (DSS; 95 per cent active), were added to the column. The sol was foamed until all foaming had ceased, which required 35–50 min, with foam removal from a port located 48 cm above the feed sol-level. After the completion of each experiment the residual sol volume was measured volumetrically, the residual concentration of trivalent iron was determined<sup>8</sup> (accurate to  $\pm 0.05$  mg/l.), and the residual concentration of DSS was measured by a two-phase titration technique<sup>10</sup>. Temperature was maintained constant at 25°C.

**Foamability.** The extreme influence of the presence of colloidal particulates on the foamability and separation of solutions containing surfactants of opposite charge to the particulates is shown in Table 1. The negatively charged stannic oxide sol was prepared by reacting sodium stannate with sulphuric acid in boiling water and by peptization with ammonium hydroxide; the pH of the sol was 7.4 (ref. 5). The feed sol, of volume 800 ml., contained 2,000 mg/l. of stannic oxide and 50 mg/l. of cetyltrimethylammonium bromide (CTAB), a cationic surface-active agent. Foam was collected from a port located 12 cm above the feed sol level. The solutions of CTAB were in distilled water. For the ferric oxide-DSS system, equivalent solutions of pure DSS were prepared with the pH lowered to approximately 2.5 with hydrochloric acid and elevated to 5.0 with sodium carbonate. In Table 1,

Table 1. INFLUENCE OF COLLOIDAL PARTICULATES ON FOAMABILITY

Stannic oxide-CTAB system		
Foaming time: 10 min		
Air rate: 2,520 ml./min		
pH, 7.4		
50 mg CTAB/l. solution	Stannic oxide (2,000 mg/l.) - CTAB (50 mg/l.) sol	
$V_f/V_i$	0.0	0.009
$\sigma_r$ , mg/l.	50.0	5.0
Air rate: 10,140 ml./min		
$V_f/V_i$	0.034	0.333
$\sigma_r$	40.0	1.0
Ferric oxide-DSS system		
Foaming time: 40 min		
Nitrogen rate: 4,500 ml./min		
pH, 5.0		
25 mg DSS/l. solution	Ferric oxide (117 mg/l.) - DSS (25 mg/l.) sol	
$V_f/V_i$	0.0	0.543
$\sigma_r$ , mg/l.	25.0	0.7
Nitrogen rate: 8,000 ml./min		
$V_f/V_i$	0.0	0.403
$\sigma_r$	25.0	0.9

$V_f$  is the volume of collapsed foam (ml.),  $V_i$  is the volume of feed sol or solution (ml.), and  $x_i$  is the concentration of surfactant in the residual sol or solution after foaming (mg/l.).

**Influence of pH.** A series of experiments was conducted to establish the effect of hydrogen ion concentration on the foam fractionation-flotation of ferric oxide-DSS sols. In order to clarify the notation used herein, for each experiment the following material balance equations may be written:

$$V_i = V_f + V_r \quad (1)$$

$$x_i V_i = x_f V_f + x_r V_r \quad (2)$$

$$z_i V_i = z_f V_f + z_r V_r \quad (3)$$

$x_i$  and  $z_i$  are the concentrations of DSS and trivalent iron in the feed sols, respectively,  $V_r$  is the volume of residual sol after foaming (ml.),  $x_r$  is the trivalent iron concentration in the residual sol, and  $z_r$  are the concentrations of DSS and trivalent iron in the collapsed foam, respectively. In these experiments, the nitrogen rate was 4,500 ml./min (at 25° C and 1 atm.), the feed concentrations of DSS were 15 and 40 mg/l., the feed concentrations of ferric oxide were 58.5 and 17.5 mg/l., and the pH was varied from 3.1 to 6.0.

Fig. 1 indicates the variation in the collapsed foam volume and in the DSS enrichment ratio ( $x_f/z_f$ ) with pH. For both sets of feed concentrations, at pH = 3.0 no foam was obtained. Elevation of pH to about 4.5 brought about extreme increases in  $V_f$  and decreases in the enrichment ratios, both of which tended to become constant at pH = 5.0. It appears that as the pH was elevated from 3.0, the ferric oxide complex was transformed by the removal of hydrogen ions from the waters of hydration, with each hydrogen ion removed yielding a hydroxide ion which remained associated with the complex, thereby reducing the charge of the complex:

where  $n$  is an integer ranging from 6 to 4, and  $m$  is an integer ranging from 0 to 2. Sebba<sup>11</sup> has discussed such

Fig. 1. Relations between  $V_f$ ,  $x_f/z_f$ , and pH

Fig. 2. Relation between  $x_r$  and  $x_i/z_i$

an interconversion of species for aluminium oxide. As the pH was raised, the charge on the hydrated complex was diminished and the formation of polynuclear species (containing oxygen bridges) was further enhanced. Such species would be more readily floated and would tend to promote foam stability. The formation of polynuclear species could be detected by optical density measurements on the feed sols, and it was found that the optical density, measured with a spectrophotometer at 500 mμ, increased with pH. The increase was more pronounced at higher trivalent iron concentrations.

For both sets of feed concentrations, the residual DSS concentrations decreased as the pH was increased, owing to the larger volumes of foam which were produced. For  $z_i = 17.5$  mg/l., the trivalent iron concentration in the residual sol decreased with increasing pH, while for  $z_i = 58.5$  mg/l.,  $z_r$  increased with increasing pH. These results are presented in Table 2.

Table 2. EFFECT OF pH ON RESIDUAL CONCENTRATIONS  
 $x_i = 40.0$  mg/l.,  $z_i = 17.5$  mg/l.

pH	$x_r$ , mg/l.	$z_r$ , mg/l.
3.1	8.0	0.35
4.0	5.0	0.30
4.5	4.2	~0.05
4.50	1.3	~0.05
4.55	1.6	~0.05
5.0	2.6	~0.05
6.0	2.0	~0.05

$x_i = 15.0$  mg/l.,  $z_i = 58.5$  mg/l.

pH	$x_r$ , mg/l.	$z_r$ , mg/l.
4.70	0.9	1.48
4.65	0.9	2.10
5.0	0.6	2.10
5.5	0.6	5.00

**Influence of concentration variations.** A second series of experiments was conducted to investigate the effect of feed concentrations of trivalent iron and DSS. In these experiments  $x_i$  was varied from 10 to 40 mg/l.,  $z_i$  was varied from 10 to 146 mg/l., the nitrogen rate was 4,500 ml./min, and the pH of each feed sol was maintained at 5.0. The residual DSS concentrations are related in Fig. 2 to the ratio of DSS to trivalent iron in the feed. As  $x_i/z_i$  was increased,  $x_r$  remained relatively constant and then rose sharply above a feed ratio of approximately 1.0. The total range of variation of  $x_r$  was 0.4–3.6 mg/l. For these same experiments, the residual trivalent iron concentrations could be related to  $x_i$  and  $z_i$  by a single equation:

$$z_r = 7.24 (10^{+5}) x_i - 9.60 z_i (3.20 \log_{10} x_i - 0.60) \quad (4)$$

For a total of 24 experiments the average deviation of values of  $z_r$  calculated with equation (4) from experimental values was 25 per cent. (Average deviation =

$$\frac{\text{calculated value} - \text{experimental value}}{\text{experimental value}} \times 100.)$$

An extensive discussion of the separation of ferric oxide (trivalent iron) has been reported<sup>7</sup>.

Fig. 3. Relations between  $x_f V_f / x_i V_i$  and  $x_i$ , with parameters of  $x_i$ .

Considering the utilization of colloidal particulates to enhance the separation of surfactants, a useful parameter is weight of surfactant removed in the foam per unit weight of trivalent iron in the feed,  $x_f V_f / x_i V_i$ . In Fig. 3 this parameter is related to  $x_i$  and  $x_i$ , and for each value of  $x_i$  it increases linearly with  $x_i$ . The slopes of the lines in Fig. 3 were found to be inverse power function of  $x_i$ , and since  $V_i$  was held constant in all the experiments the following equation was obtained:

$$x_f V_f = 1.692 x_i^{-0.032} x_i \quad (5)$$

Equation (5) shows that the weight of surfactant carried

into the foam was directly proportional to the feed concentration of surfactant and was a rather weak function of the feed trivalent iron concentration. The average deviation for equation (5) was 2.1 per cent for the 24 experiments. For constant  $x_i$ , as  $x_i$  was increased,  $V_f$  increased and  $x_f$  decreased, with the rates being virtually equal.

**Conclusions.** (1) The addition of colloidal particulates to solutions containing oppositely charged surfactants produces large increases in foamability, thereby promoting the separation of the surfactant into the foam. Through the addition of such particulates, the foam fractionation mechanism is replaced by a froth flotation mechanism, and the particulates together with the adsorbed surfactant are readily carried into the foam owing to preferential adsorption at the gas-solution interfaces associated with the bubbles.

(2) For the DSS-ferrie oxide system, pH has a pronounced effect on the quantity of foam produced and on the DSS enrichment ratio. This behaviour is magnified over a rather narrow pH range of 4.4-5.0, and is apparently caused by the interconversion of ferrie oxide complexes.

(3) For the DSS-ferrie oxide system at a constant pH of 5.0, the residual concentration of DSS is related to the feed ratio of DSS to trivalent iron, increasing sharply above a feed ratio of 1.0. The weight of DSS carried into the foam is directly proportional to the feed concentration of DSS and is a weak function of the feed concentration of trivalent iron.

## INVERSE RELATIONSHIP OF GLUCOSE-6-PHOSPHATE LEVELS AND GLUCOSE UTILIZATION IN 6C3HED LYMPHOMA

By PROF. CHARLES E. WENNER

Department of Experimental Biology, Roswell Park Memorial Institute, New York State Department of Health, Buffalo, New York

EVIDENCE has accumulated that glucose-6-phosphate inhibition of the hexokinase reaction may be a factor in the utilization of carbohydrate in cells. Product inhibition has been observed with hexokinase isolated from several mammalian tissues, both neoplastic and non-neoplastic<sup>1,2</sup>. The possible regulation of glucose utilization in hexokinase activity is further suggested by the finding of Hees and Chance<sup>3</sup> that addition of glucose to Ehrlich ascites tumour cells increases the level of glucose-6-phosphate to 1  $\mu$ mole/g of cells, that is, a concentration greater than 1 mM if the space occupied by cell matter is taken into consideration. In addition, the concentration of glucose-6-phosphate was highest at the time of maximal inhibition of glucose utilization, and the initially rapid rate was associated with the lower levels of hexose monophosphate; furthermore, the activity of hexokinase as well as phosphofructokinase of Ehrlich ascites tumour is relatively low in comparison with the other enzymes of

glycolysis, as reported by Racker and Wu<sup>4</sup>, and is thus a likely candidate for a controlling step.

This concept that product inhibition of hexokinase is an important regulatory factor in glucose utilization within the cell has recently been given added support by the work of Rose *et al.*<sup>5</sup> in an investigation of erythrocytes in which a linear relationship was observed when the reciprocal of the glucose-6-phosphate level was plotted against the rate of glucose utilization. These workers used an artificial electron acceptor, methylene blue, to stimulate glucose utilization by means of the phosphogluconate pathway, and inosine, which is utilized preferentially, to inhibit glucose uptake.

It was, therefore, of interest to examine the relationship of glucose-6-phosphate levels and rates of glucose utilization in cells capable of respiration in order to provide further understanding of the mechanism of the Pasteur effect in ascites tumour cells. The 6C3HED mouse

Fig. 1. Conditions are the same as described in Table 1. The symbols represent the following conditions: ○, control; ●,  $\beta$ -OH butyrate,  $1 \times 10^{-3}$  M; □, antimycin A,  $1.7 \times 10^{-4}$  M; ◆, ethanol,  $6.5 \times 10^{-4}$  M; △, rotenone,  $7 \times 10^{-5}$  M; ◇, nitrogen as the gas phase; ▲, antimycin A,  $8.4 \times 10^{-4}$  M; ■, rotenone,  $1.4 \times 10^{-5}$  M.

lymphoma is useful for this purpose since these cells have a low rate of glucose utilization and thus may be more susceptible to product inhibition. In addition, the changes in glucose utilization, induced by a wide variety of compounds, are more marked than in the Ehrlich ascites tumour cells.

For example, it was noted that  $\beta$ -OH butyrate decreases glucose utilization in this neoplasm without having observable effects on respiration, in contrast to tumours such as the Ehrlich and hyperdiploid ELD ascites form where  $\beta$ -OH butyrate had no effect on glycolysis. Also, ethanol has been observed to inhibit the oxygen uptake of rat liver mitochondria<sup>8</sup>, and preliminary investigations indicated that this lipid-soluble compound inhibits respiration and stimulates glucose utilization in the 6C3HED lymphoma. In addition, two well-known inhibitors of respiration, antimycin A and rotenone, produce the characteristic stimulation of glucose uptake and lactate accumulation in these cells, resembling the effect of anaerobiosis, and the effect of these inhibitors can be investigated at different concentrations to give a wide range of rates of glucose utilization.

6C3HED lymphoma cells were maintained in female C3H/ST mice and were collected seven days after implantation. The ascites tumour cells were isolated by low-speed centrifugation, were washed twice with  $\text{Ca}^{++}$ -free Krebs-Ringer phosphate and were resuspended in this medium.

The procedures of incubation and methods of analyses were essentially the same as described in a previous paper<sup>7</sup> and glucose-6-phosphate was determined by the method of Hohorst<sup>9</sup>.

Initially the effect of time on glucose utilization was examined, and like Ehrlich Lettré ascites tumour cells which show an initial burst of glucose utilization in the first 30 sec, and then a marked decrease in the steady state, the rate of glucose utilization in the lymphoma cells, and lactate production as well, was lower after this initial transient and linear for at least 20 min. The steady-state level of glucose-6-phosphate was reached within 80 sec, and did not change from this initial maximum.

The distribution of glucose-6-phosphate in the cells and the medium in which they were suspended was next investigated since the relationship between glucose-6-

phosphate level and rate of glucose utilization based on end-product inhibition would depend on the intracellular glucose-6-phosphate concentration. On centrifugation at 5° C of cells incubated with glucose, it was found that glucose-6-phosphate was associated entirely with the cell fraction, indicating that glucose-6-phosphate was completely intracellular.

An experiment, depicted in Fig. 1, was then carried out in which the rate of glucose utilization was modified by a wide variety of agents. The values for the levels of glucose-6-phosphate were plotted against the measurements of glucose utilized. In this typical experiment there is a linear inverse relationship between these two variables, and the relationship holds regardless of whether ethanol or the conventional inhibitors of respiration were used to stimulate glucose utilization or whether  $\beta$ -OH butyrate was used to inhibit glucose utilization.

The effects of these substances on the related processes are reported in Table 1. In addition to the measurements of respiration the values for the end-products of glycolysis are also reported in Table 1, and it was observed that the ratio of lactate/glucose increased as the degree of respiratory inhibition increased.

It is apparent that glycolysis was not stimulated to the same extent by respiratory inhibitors and anaerobiosis. Furthermore, the degree of stimulation of glycolysis was not only dependent on the inhibitor concentration at low concentrations but also at high concentrations. In the case of rotenone, glycolysis reached an optimum, and then a slight decline was observed. The decline was significant, since it could be reproduced in experiments where higher concentrations of rotenone were used. This decline is considered to arise from the breakdown of ATP required for glucose phosphorylation since the inhibition of glucose utilization and lactate production was also observed with progesterone, amytal or antimycin at concentrations which stimulate ATPase.

The finding that ethanol inhibits respiration and stimulates glycolysis in a manner similar to the other respiratory inhibitors suggests that lipid solubility is important in influencing these relationships.

In contrast, the inhibition by  $\beta$ -OH butyrate of glucose utilization cannot be attributed to the Pasteur effect since in none of the experiments carried out with  $\beta$ -OH butyrate did it produce a significant change in the rate of respiration.

The possibility that  $\beta$ -OH butyrate might influence glucose utilization by interfering with the reactions of glycolysis *per se* was ruled out by the observation that  $\beta$ -OH butyrate under similar conditions was not observed to have any effect on anaerobic glycolysis.

In order to determine whether the effect of  $\beta$ -OH butyrate is mediated by mitochondrial interactions, the effect of other diphosphopyridine nucleotide (DPN)-dependent substrates as malate, fumarate, citrate, glutamate and  $\alpha$ -ketoglutarate was examined. The

Table 1. EFFECT OF SUBSTANCES WHICH MODIFY GLUCOSE UTILIZATION ON RELATED PROCESSES

Additions	Final concentration (Molar)	Oxygen uptake (μmoles)	Glucose utilized (μmoles)	Lactate accumulated (μmoles)	Lactate/Glucose
Control		6.4	5.2	5.1	0.99
Antimycin	$1.7 \times 10^{-4}$	3.5	5.9	6.5	1.11
	$3.4 \times 10^{-4}$	1.9	10.8	16.1	1.49
	$6.8 \times 10^{-4}$	0.5	12.0	15.6	1.31

Citrate	5.1	3.1	1.5	0.034
Glutamate	5.0	1.5	1.3	0.048

\* At zero time this value was 0.005 μmoles per flask.

† At zero time, this value was nil.

COSHMD ascites tumour cells equivalent to 25 mg dry tissue weight were incubated as described in Table 1 for 30 min at 38° C. All substrates including glucose, which was present in all flasks, were in a final concentration of 0.01 M.

experiment reported in Table 2 indicates that with the exception of α-ketoglutarate these substrates produced decreases in glucose utilization with a corresponding linear increase in the levels of glucose-6-phosphate. Furthermore, there were no significant changes in the rate of respiration. It would therefore appear that the effect of β-OH butyrate is mediated by the electron transport system and/or its associated phosphorylation.

It is also to be noted that glutamate, citrate and α-ketoglutarate inhibited lactate production, as did β-OH butyrate. It is also possible that malate and fumarate cause an inhibition of lactate production from glucose, but the inhibition may be masked by the production of lactate from these metabolites.

It is difficult to correlate hexokinase activity and glucose-6-phosphate level on a quantitative basis in the intact cell in view of the many factors which influence hexokinase activity. Since glucose-6-phosphate and ADP compete with ATP for the enzyme<sup>1,2</sup>, the  $K_i$  of product inhibition is also dependent on the concentration of these nucleotides. It is nevertheless of interest to calculate the approximate intracellular level of glucose-6-phosphate. The amount present in the steady state was observed to be 0.05 μmoles/30 mg dry tissue weight or 0.2 g wet weight of cells, that is, c. 0.25 μmoles/ml. If the concentration is calculated on the assumption that 80 per cent of the packed volume is water<sup>3</sup>, the value obtained is  $3 \times 10^{-4}$  M, which approximates that of the  $K_i$  observed for several mammalian tissue hexokinases<sup>1,4</sup>.

The present experiments indicate that the hexokinase reaction is completely responsive to a wide range of glucose-6-phosphate levels as had been observed in the erythrocyte by Rose<sup>5</sup>. The present work, where several respiratory inhibitors were used to alter glucose utilization, indicates that product inhibition of the hexokinase reaction is an important factor in glucose utilization in this neoplasm under aerobic and anaerobic conditions, and that the Pasteur effect in this neoplasm is possibly mediated by glucose-6-phosphate inhibition.

However, it is not yet possible to determine whether hexokinase is the major pacemaker in the overall reactions of glycolysis in these cells having a low rate of glucose utilization. The possibility that the relationship between glucose-6-phosphate levels and glucose utilization observed in these experiments is secondary to a change in some intermediate or effect which varies directly with glucose-6-phosphate, as fructose-6-phosphate or phosphofructokinase activity, cannot as yet be ruled out. Regen *et al.*<sup>1,6</sup> have observed that the activity of hexokinase in heart muscle was found to be inversely related to the glucose-6-phosphate levels, which they considered were governed to a large extent by the activity of phosphofructokinase on the basis that, with anoxia, phosphofructokinase activity was increased, as apparent from a lowering of the substrate concentration and an increase in the product concentration associated with a faster glycolytic flow.

In this regard, Hees and Chance<sup>7</sup> observed relatively high concentrations of fructose-1,6-diphosphate (1–3 mM) in ascites tumour cells having a high rate of glucose utilization, a finding which suggests that hexokinase activity does not control the overall reactions of glycolysis

in these cells under the conditions of their experiments. Whatever the means by which the primary control occurs, it is nevertheless necessary that there must also be control over the initial irreversible step of glycolysis since, as pointed out by Lonberg-Holm<sup>13</sup>, failure to exhibit control would lead to endless increases in intracellular phosphates.

It is not anticipated that the relationship between glucose utilization and hexokinase product concentrations will hold under those conditions which greatly alter phosphate concentrations, since it has been observed that inorganic phosphate partially releases the glucose-6-phosphate inhibitions<sup>8,14</sup>. In our earlier investigations, it had also been observed that glucose utilization by way of the hexose monophosphate oxidative shunt pathway in these cells was enhanced by the artificial electron acceptor, phenazine methosulphate, and the addition of higher levels of inorganic phosphate produced a further stimulation of this pathway.

The observation that β-OH butyrate and other DPN-dependent oxidizable substrates inhibit glucose utilization might be explained on the basis that these substrates compete with pyruvate for the respiratory chain. However, the finding that lactate is also inhibited by these substrates suggests that this explanation does not suffice for the decreased glucose utilization. Furthermore, the possibility that all these substrates compete with glucose for entry into the cell also appears unlikely.

The finding that glucose utilization can be regulated by several DPN-dependent oxidizable substrates is of especial interest since it occurs under conditions where respiration is unchanged. It is possible that the changes which occur under these conditions are analogous to those which occur in the operation of the Pasteur effect, and since glucose utilization can be readily manipulated by varying the concentration of the DPN-dependent substrate, an investigation conducted with this convenient system may provide considerable insight into this incompletely understood control mechanism. In particular, it is of interest to investigate the influence of these substrates on changes occurring at the mitochondrial pyridine nucleotide level.

It should also be pointed out that the Crabtree effect is much less pronounced in this neoplasm than that observed in the Ehrlich ascites tumour cells<sup>15</sup>, and that the intracellular concentration of glucose-6-phosphate of the lymphoma (c.  $3 \times 10^{-4}$  M) is considerably lower than that calculated on a similar basis from the data reported by Hees and Chance<sup>7</sup> on the Ehrlich carcinoma, that is,  $1.3 \times 10^{-4}$  M. In view of this correlation and the recent demonstration that respiration of mitochondria isolated from ascites tumour cells is inhibited by glucose-6-phosphate accumulation<sup>16</sup>, it is suggested that the level of glucose-6-phosphate plays a part in the inhibition of respiration produced on glucose addition.

## NUCLEATING SUBSTANCE(S) IN HUMAN SALIVA

By DR. RALPH G. EILBERG, DR. DAVID GOULD and DR. ALBERT E. SOBEL\*

Beth Israel Hospital, New York, and Colgate Palmolive Research Laboratories, New Brunswick, New Jersey

**F**UNDAMENTAL step in the process of mineralization is the formation of nuclei of crystal growth. In this connexion, the isolation of substances that can induce nucleation is basic to the understanding of calcification in living organisms. As a result of the interest directed toward the calcification of bone, collagen has been identified as a substance capable of inducing the formation of nuclei of hydroxyapatite crystal growth from a metastable solution<sup>1-3</sup>. Mineralization occurs, however, in many areas other than bone, and in some cases minerals other than hydroxyapatite are formed (for example, oral calculi, kidney stones). It is of interest to study these systems, as new calcifying catalysts may be discovered as a result<sup>4</sup>.

We wish to report evidence indicating the presence of a substance(s) in human saliva capable of inducing the formation of nuclei of hydroxyapatite crystal growth.

Saliva preparations which induce calcification have been reported previously<sup>5,11</sup>. This calcification was interpreted as due to nucleation. These investigators, however, did not employ sensitive methods for detecting pre-existing nuclei (seed crystals)<sup>6,12</sup>. One billion nuclei of hydroxyapatite (seed crystals)  $25 \text{ \AA} \times 50 \text{ \AA} \times 100 \text{ \AA}$  weigh only  $4 \times 10^{-4} \text{ \mu g}$  and thus will escape detection by the usual chemical methods, but can be detected by other means recently developed<sup>6,12</sup>. With these new methods of testing for pre-existing nuclei<sup>6,12,13</sup> it appears from the present investigations that the preparations of the foregoing workers<sup>5,11</sup> were already 'nucleated'. In the presence of pre-existing nuclei, calcification represents crystal growth and does not provide rigorous evidence for the existence of an organic compound(s) capable of inducing nucleation. Wasserman *et al.*<sup>14</sup> examined calcification of plaque material *in vitro*. Von Der Fehr and Brudevold<sup>11</sup> criticized this work, suggesting that pre-existing nuclei may be present. In the same paper Von Der Fehr and Brudevold described the preparation of a calcifiable material by alternate dipping and drying of paper disks into saliva. According to the authors, the material contained "minute mineral deposition". Material prepared in our laboratories in a manner similar to that of Von Der Fehr and Brudevold was already 'nucleated' (Tables 1 and 2). In the hope of obtaining nuclei-free material, these investigators<sup>11</sup> have demineralized formaldehyde-treated calcified saliva matrix with EDTA at a pH of 7.0 for 24 h. The organic residue remaining did re-mineralize. However, nuclei for hydroxyapatite crystal growth still remain after decalcification for 24 h. in EDTA at a pH of 7.0 as shown in our laboratories<sup>14</sup>. Moreover, the formaldehyde-treated saliva matrix represents a derivative.

The saliva used in our work was obtained from human donors who chewed paraffin and it was used within 2 h. The saliva with or without treatment was centrifuged at 8,720*g* at low temperature in the Spinco preparative ultracentrifuge. The supernatant fluid was practically bacteria free.

The extracts used in this work were prepared as follows: 20 ml. of centrifuged saliva were each placed in hemispherical troughs and two glass slides were mechanically rotated through each one of these troughs for 3 h at 0.5 r.p.m.<sup>15</sup>. Air was blown past the slides so that, as the slides emerged from the troughs, drying took place. In this manner, a film was deposited at one end of the slide. Such film was practically bacteria free, although it contained considerable bacteria without the centrifuging step. The

film represents a continuous concentration of the solid in air and a partial dissolution of the dried material, the more soluble material being redissolved leaving the more insoluble material on the slide.

The films were placed for 20 h in solutions similar to those which were utilized in our earlier studies for calcification *in vitro* of hypertrophic epiphyseal cartilage and collagen<sup>1,3,6,8</sup>. Thymol was added at a level of 10 mg/l. The calcifying solution contained 70 mM NaCl, 22 mM NaHCO<sub>3</sub>, and 5 mM KCl per litre. Calcium was added as CaCl<sub>2</sub>. Phosphate phosphorus was added as the NaH<sub>2</sub>PO<sub>4</sub>: Na<sub>2</sub>HPO<sub>4</sub> mixture (4:1). The pH was 7.3 and the temperature was 37° C. In some instances, radioactive calcium-45 or phosphorus-32 labelled phosphate or both were added to the solution. The calcified substances were then counted, using a gas flow counter with a high-speed scaler or an ambient type liquid scintillation counter, and the amount of incorporated calcium and phosphorus calculated.

As seen in Table 1, films prepared from centrifuged saliva contained considerable calcium and phosphate, suggesting the presence of nuclei (seed crystals). Evidence that the calcium and phosphate are present in the form of pre-existing nuclei (seed crystals) is given in Table 2. There is considerable calcification after treatment with CuCl<sub>2</sub>, which would inactivate nuclei-free matrix as seen in Table 3. Such films therefore are not suitable for establishing the existence of nucleating substance(s) in saliva.

To prevent the formation of calcium phosphate nuclei (seed crystals), removal of calcium was undertaken. For this purpose, an aliquot of saliva was titrated with disodium EDTA<sup>16</sup> and the calculated amount of EDTA necessary to bind all the calcium was added to another portion of saliva. However, saliva treated in this manner gave no film. The EDTA changed the solubility of the material. The air-dried solid re-dissolved each time the slide was rotated into the saliva. To overcome this difficulty, an amount of oxalic acid equivalent quantitatively to the amount of calcium present was added to saliva. This was followed by centrifugation, which

Table 1. Ca AND P\* CONTENT OF FILMS PREPARED FROM CENTRIFUGED SALIVA

Sample No	Ca and P Incorporated (μg)
1	Ca 69.1
	P 26.4
2	Ca 86.3
	P 38.0
3	Ca 120.0
	P 54.5
4	Ca 124.0
	P 43.6

The total Ca and inorganic phosphate P were determined in the initial saliva. This was followed by the addition of radioactive <sup>45</sup>Ca and <sup>32</sup>P. The Ca and P contents of film were then calculated from the counts in the liquid scintillation counter.

\* Phosphate P.

Table 2. INFLUENCE OF CuCl<sub>2</sub> ON THE CALCIFICATION OF FILMS PREPARED FROM CENTRIFUGED SALIVA

Treatment	Ca and P Incorporated (μg)
Control	Ca 908
	P 734
Control	Ca 556
	P 416
Control	Ca 1,020
	P 722

	P 288
CuCl <sub>2</sub> (1 mM)	Ca 404
	P 357

Films prepared from the supernatant of saliva centrifuged at 8,720*g* (ave.) were placed in 1 mM/l. CuCl<sub>2</sub> solution for 10 min. Controls were placed in H<sub>2</sub>O. After 10 min all slides were rinsed in water, then placed in calcifying solution (15 mg per cent Ca · 5 mg per cent P) to which <sup>45</sup>Ca and <sup>32</sup>P were added. After 20 h the films were removed from the calcifying solution, rinsed and counted, using an ambient type liquid scintillation counter.

Table 3. THE INFLUENCE OF  $\text{CuCl}_2$  ON THE CALCIFICATION OF 'NUCLEATED' AND 'NON-NUCLEATED' SALIVA FILMS

Treatment	Ca and P incorporated ( $\mu\text{g}$ )
Control	Ca 75.1 P 89.4
Control	Ca 73.8 P 40.8
$\text{CuCl}_2$ (1 mM/l)	Ca 1.66 P 0.739
$\text{CuCl}_2$ (1 mM/l)	Ca 1.50 P 0.691
Nucleated then $\text{CuCl}_2$ (1 mM/l)	Ca 147.0 P 83.1
Nucleated then $\text{CuCl}_2$ (1 mM/l)	Ca 44.2 P 22.0

Controls were placed in water for 10 min, then in labelled calcifying solution for 20 h. Non-nucleated preparations were placed in 1 mM/l  $\text{CuCl}_2$  for 10 min and in labelled calcifying solution for 20 h. Preparations were nucleated by placing them in unlabelled calcifying solution (15 mg per cent Ca, 5 mg per cent P) for 3 h. After nucleation, they were placed in 1 mM/l  $\text{CuCl}_2$  for 10 min and in labelled calcifying solution for 20 h.

removed the calcium oxalate formed and saliva sediment. This procedure removed 99 per cent of the calcium in solution as shown by calcium-45 tracer. Our further investigations were carried out with such calcium-free saliva. Unless treated with inactivating agents, the films mineralized with the formation of apatite as shown by X-ray diffraction. This mineralization can be readily shown visually by a decisive increase in opacity.

Since there was the possibility of traces of calcium oxalate remaining in our preparation, the nucleating properties of calcium oxalate prepared by adding oxalic acid in an amount equivalent to the EDTA titration of a  $\text{CaCl}_2$  solution was investigated. Such calcium oxalate induced nucleation, but this nucleation was not inhibited by  $\text{CuCl}_2$  under conditions which inhibit nucleation of our saliva extract films<sup>11,12</sup> (Table 3). Another indication that a nucleating substance is present in saliva is calcification of a fraction obtained by passing decalcified centrifuged saliva through a 'Sephadex G-25' column. These fractions were obviously calcium oxalate free.

The next question was whether the inorganic phosphate present in the film was responsible for the calcification. By adding phosphorus-32 labelled phosphate to the saliva and establishing the initial inorganic phosphate and determining the phosphorus-32 content of the films of several slides, it was found that the film per slide contained 4.0 micrograms inorganic  $\text{PO}_4$ . After soaking for 10 min in water which preceded our calcification, the organic phosphorus was 1.3  $\mu\text{g}$ . The 30 ml. of calcifying solution which we employed contained 1,670  $\mu\text{g}$  of  $\text{PO}_4$  phosphorus. Thus, it may be concluded: (1) that the amount of  $\text{PO}_4$  present cannot account for inducing the calcification; (2) that most of the  $\text{PO}_4$  dried on the film when in air re-dissolved on re-immersion into the saliva, indicating again that the formation of a film represents a concentration of the less soluble portions of saliva.

Table 3 presents typical replicate investigations of films prepared from calcium-free saliva. The saliva film induces mineralization. Prior treatment with 1 mM  $\text{CuCl}_2$  prevents this mineralization. However, if the slides are exposed to the calcifying solution (15 mg per cent calcium  $\times$  5 mg per cent phosphorus) for 3 h, at which time an increase in calcium phosphate is scarcely detectable, the film continues to mineralize almost to the same degree as the water-treated controls. Thus,  $\text{CuCl}_2$  can be used to distinguish between 'nucleated' and 'non-nucleated' saliva extract film, just as was the case for collagen and hypertrophic epiphyseal cartilage<sup>11,12</sup>.

Table 4 shows that pre-nucleated saliva will continue calcifying at products lower than required for initiating calcification, just as was the case for hypertrophic epiphyseal cartilage and collagen<sup>6,14,15</sup>. This is a further indication that the calcium-free film was not pre-nucleated.

The calcium-free nucleating substance(s) mineralizes at a calcium  $\times$  phosphorus product of 35 as seen in Table 5. Using the same calcifying solutions, this minimum is 60 for acid-soluble collagen, 50 for acid-insoluble collagen and 30 for rachitic epiphyseal cartilage<sup>6,12</sup>. Thus, the nucleating catalyst present in saliva appears to be more

Table 4. CALCIFICATION OF 'NUCLEATED' AND 'NON-NUCLEATED' SALIVA MATRIX

Treatment	Calcium incorporated ( $\mu\text{g}$ )
Placed in low-strength calcifying solution	5.47
Placed in low-strength calcifying solution	1.85
Nucleated then placed in low-strength calcifying solution	202.0
Nucleated then placed in low-strength calcifying solution	248.0

Two preparations were placed in the labelled calcifying solution (12 mg per cent Ca, 2.5 mg per cent P) for 20 h. Two other preparations were nucleated by placing them in unlabelled calcifying solution (15 mg per cent Ca, 5 mg per cent P) for 3 h. After nucleation they were placed in the labelled calcifying solution (12 mg per cent Ca, 2.5 mg per cent P) for 20 h.

4	5	0.211	0.053
4	5	0.299	0.099

Slides were placed in water for 10 min and then in labelled calcifying solution for 20 h.

effective than collagen, although not quite as good as the complete system present in the matrix of hypertrophic epiphyseal rachitic cartilage.

It is of interest to note that  $\text{Cu}^{++}$  ion uptake by the saliva extract is maximal at the end of 1 min as shown by radioactive tracer studies. A clue of the nature of copper inhibition with nucleation may be present in the investigations of Malik and Salahuddin with gelatin<sup>17</sup>. They found that copper binds  $\alpha$ -amino groups and carboxyl groups. That both amino and carboxyl groups are involved in nucleation is a reasonable hypothesis and will be explored further.

$\text{ZnCl}_2$  behaves similarly in detecting nucleation, but was not investigated exhaustively.

The saliva extract was analysed for total nitrogen and results indicate the value to be 4.8 per cent. The results of amino-acid analysis are shown in Table 6. The nitrogen percentage, the number of amino-acids and amide links in the infra-red, indicate the presence of high amounts of protein or polypeptide in the preparation.

To obtain some preliminary information concerning the mechanism of nucleation, the saliva extract was placed in  $\text{HNO}_3$  at pH 4.5 at room temperature for varying lengths of time. The nitrous acid was prepared by adding sufficient 1.0 molar HCl to 1 molar  $\text{NaNO}_2$  to reach a pH of 4.5. After the material was removed from the  $\text{HNO}_3$ , it was rinsed and placed in calcifying solution (15 mg per cent calcium; 5 mg per cent phosphorus) at 37° C for 20 h. The nitrous acid inactivated calcifiability in as little as 3 sec (Table 7). The control placed in 1.0 molar NaCl adjusted to pH 4.5 with HCl was far less effective than the nitrous acid solution in inactivating

Table 6. AMINO-ACID COMPOSITION OF CALCIFYING SALIVA EXTRACT

Amino-acid	Moles per 2-mg sample
Aspartic	0.180

2 mg of material prepared from oxalate decalcified saliva supernate was scraped off glass slides, placed in 6 N HCl in sealed glass tubes at 110° C for 6 h, dried to remove HCl and analysed on an amino-acid analyser (courtesy of Wm. Shoemaker, Michael Reese Hospital, Chicago).

Table 7. SURVIVAL OF CALCIFIABILITY ON EXPOSURE TO NITROUS ACID WITH NaCl:HCl MIXTURE AS A CONTROL

Time of exposure to nitrous acid	Calcium incorporated ( $\mu$ g)	Time of exposure to NaCl:HCl	Calcium incorporated ( $\mu$ g)
Control	200	Control	240
Control	216	Control	208
3 sec	17.2	3 sec	205
3 sec	12	3 sec	174
5 min	3	5 min	197
5 min	2	5 min	109
10 min	4	10 min	94
10 min	2	10 min	121

Saliva extracts were placed in 1.0 molar  $\text{HNO}_3$  solution at pH 4.5 or in 1.0 molar NaCl solution with 1.0 molar HCl added to bring the pH to 4.5 for varying lengths of time. They were then rinsed in water and placed in calcifying solution (15 mg per cent Ca, 5 mg per cent P) containing  $^{45}\text{Ca}$  for 20 h. Controls were placed in water 10 min and in the calcifying solution 20 h.

calcifiability (Table 7). The results indicate that amino-groups may play a part in nucleation by this material.

Further evidence indicating the involvement of amino-groups is the fact that dinitrofluorobenzene treatment also inhibits calcifiability.

The results indicate the importance of testing for pre-existing nuclei before proposing that a substance is capable of inducing the formation of nuclei. For this purpose, methods for detecting nuclei more decisive than chemical analysis are proposed in this paper. The evidence for the presence of a nucleating substance(s) in human saliva is presented and is proposed as a significant factor in the formation of oral calculi. We hope that the properties of the purified nucleating fraction of saliva will shed further light on the mechanism and structural

aspects required for inducing the formation of nuclei of hydroxyapatite and related substances.

## ACTION OF THYROID-STIMULATING HORMONE ON RIBONUCLEIC ACID SYNTHESIS IN THYROID SLICES AND IN ISOLATED THYROID NUCLEI

By DOROTHY J. BEGG and PROF. H. N. MUNRO

University Department of Medicine, Royal Infirmary, and Institute of Biochemistry, University of Glasgow

**P**ROLONGED administration of thyroid-stimulating hormone (TSH) causes an increase in the RNA content of the thyroid gland<sup>1,2</sup>, followed by an increment in DNA content due to cell multiplication. Using calf thyroid tissue slices, Hall<sup>3</sup> showed that TSH increases the uptake of  $^{14}\text{C}$ -formate by the purine bases of the tissue RNA after incubation for 3 h, and attributed this effect to stimulation of synthesis of purine ribonucleotides caused by greater formation of ribose in the presence of TSH. In addition, he observed that  $^{14}\text{C}$ -adenine incorporation into the RNA of thyroid slices was raised by addition of TSH to the medium. We have examined the time-course of  $^{14}\text{C}$ -adenine incorporation into the RNA of thyroid slices during incubation with TSH. These experiments demonstrated an effect on nuclear RNA labelling which was confirmed by incubation of isolated nuclei with  $^{14}\text{C}$ -adenine in the presence of TSH.

Slices of sheep thyroid gland were prepared using the Mollwain chopper<sup>4</sup> and were incubated in Krebs-Ringer phosphate medium<sup>5</sup> pH 7.4 containing 100 mg glucose/100 ml. and an amino-acid mixture<sup>6</sup>, together with 100 units penicillin/ml. to eliminate bacterial growth during incubation. Tissue slices of about 400 mg were suspended in 4 ml. medium and 5  $\mu$ c. 8- $^{14}\text{C}$ -adenine and 0.4 units TSH (Armour 'Thytropar') were added to this volume, to give a final concentration of 0.1 units/ml. Incubation was carried out over a 3-h period in an atmosphere of oxygen, samples being taken at 0.5-h intervals. The slices were then washed with fresh Krebs-Ringer medium to remove free isotope, followed by homogenization in 0.25 M sucrose containing 0.001 M  $\text{MgCl}_2$  and 0.002 M  $\text{CaCl}_2$ . After removal of debris and unbroken cells by centrifugation at 100g for 5 min, the supernatant fluid was layered on to 0.35 M sucrose and a crude nuclear fraction was spun down at 600g for 10 min, the cell cyto-

plasm remaining in the lighter fraction. The nuclei were then purified by spinning through 2.2 M sucrose, as described elsewhere<sup>7</sup>. The RNA contained in the nuclear and cytoplasmic fractions was isolated as described in detail elsewhere<sup>7</sup> by the modified Schmidt-Thannhauser procedure of Fleck and Munro<sup>8</sup>. The nuclear and cytoplasmic fractions were then treated with cold 0.2 N  $\text{HClO}_4$  containing 2 mg/ml.  $^{14}\text{C}$ -adenine and were washed three times with 0.2 N  $\text{HClO}_4$  to remove acid-soluble small molecules. Bovine serum albumin (2 mg per sample) was added to the purified nuclei before cold acid precipitation, in order to ensure an adequate precipitate. After treatment with cold  $\text{HClO}_4$ , the residue of protein and nucleic acids was digested for 1 h in 0.3 N KOH at 37° and the DNA and protein removed by acidifying the digest to 0.2 N with  $\text{HClO}_4$ . The activity of the supernatant fraction was measured in a gas-flow counter and compared with its RNA content by ultra-violet absorption at 260 m $\mu$ . The specific activity of the RNA is expressed as c.p.m./mg RNA.

Fig. 1 shows uptake of  $^{14}\text{C}$ -adenine into nuclear and cytoplasmic RNA at various times of incubation of tissue slices for periods up to 3 h. Addition of TSH at the start of incubation had no effect on RNA incorporation until 1 h had elapsed, when an increase in nuclear RNA uptake commenced; the action of TSH on RNA labelling was not apparent in the cytoplasmic fraction until some 2 h of incubation, a finding compatible with transfer of RNA from nucleus to cytoplasm. The effects of inhibitors of protein synthesis (puromycin) and DNA-primed RNA synthesis (actinomycin D) were examined in this system (Table 1). When puromycin was added at the start of incubation, it reduced uptake of  $^{14}\text{C}$ -adenine into nuclear RNA by 60 per cent, and completely eliminated the stimulant action of TSH. When this inhibitor

Fig. 1. Uptake of  $^{14}\text{C}$ -adenine by the RNA of thyroid cell nuclei (upper graph) and cytoplasm (lower graph) during *in vitro* incubation of slices of sheep thyroid gland in the presence or absence of thyroid-stimulating hormone (0.1 I.U./ml.). Each point is the mean result of two experiments.

was added after 1 h of incubation, it still reduced  $^{14}\text{C}$ -adenine incorporation, but the action of TSH added at the start of incubation was now fully effective. This suppression of TSH action by treatment with puromycin at the start of incubation suggests that the mechanism involves synthesis of protein during the 1-h period before the increased  $^{14}\text{C}$ -adenine uptake commences (Fig. 1). Addition of actinomycin D at the start of incubation greatly reduced  $^{14}\text{C}$ -adenine incorporation and suppressed the action of TSH (Table 1). When added after 1 h of incubation, the effect of this inhibitor on RNA synthesis was still apparent; a small stimulant action of TSH was, however, obtained.

Table 1. ADENINE UPTAKE BY NUCLEAR RNA DURING *in vitro* INCUBATION OF THYROID SLICES WITH  $^{14}\text{C}$ -ADENINE AND THYROID STIMULATING HORMONE FOR A 3-H PERIOD

Time of adding inhibitor	Control slices	$^{14}\text{C}$ -Adenine uptake (c.m.p./mg RNA) TSH-treated slices	Increase
<b>Puromycin addition.</b>			
None	53,500	75,800	+21,800
At 0 h	21,600	16,800	0
At 1 h	25,400	45,200	+19,800
<b>Actinomycin addition.</b>			
None	14,200	18,200	+4,000
At 0 h	2,300	2,100	0
At 1 h	6,700	7,200	+700

The hormone (0.1 I.U./ml.) was added at the start of incubation. Puromycin (100  $\mu\text{g}/\text{ml}$ . medium) and actinomycin (10  $\mu\text{g}/\text{ml}$ . medium) were added at various times during the course of the 3-h incubation. The figures are the mean results of two experiments with each inhibitor.

Since the stimulant action of TSH was more extensive and occurred at an earlier time in the case of nuclear RNA, we examined the effect of TSH on uptake of  $^{14}\text{C}$ -adenine by isolated thyroid nuclei. Nuclei, prepared from sheep thyroid glands as already described here, were suspended in the nuclear incubation medium described by Allfrey, Mirsky and Osawa<sup>8</sup>, the pH of incubation being 7.1. Thyroid nuclei containing 400  $\mu\text{g}$  DNA were added to 1 ml. medium, which also contained 1  $\mu\text{C}$ .  $^{14}\text{C}$ -adenine. At various times of incubation up to 60 min, the reaction was terminated by plunging the sample tubes into a freezing mixture (ethanol-solid carbon dioxide). They were then treated as described here to extract RNA and to measure its specific activity. Fig. 2

Table 2. EFFECT OF THYROID STIMULATING HORMONE ON INCORPORATION OF DIFFERENT RNA PRECURSORS INTO ISOLATED THYROID NUCLEI INCUBATED IN THE PRESENCE OR ABSENCE OF NUCLEOTIDE TRIPHOSPHATES

Labelled precursor	Addition of triphosphates	Uptake of label into RNA (c.m.p./mg RNA)		
		Control nuclei	TSH-treated nuclei	Difference
$^{14}\text{C}$ -adenine	-	703	1,140	+443 (63%)
$^{14}\text{C}$ -adenine	+	982	1,308	+326 (33%)
$\alpha$ -P-UTP	+	280	473	+193 (69%)

Where indicated, 0.1 I.U./ml. of thyroid stimulating hormone and 0.4  $\mu\text{mole}/\text{ml}$ . of ATP, CTP, GTP and UTP were added to the medium. The  $\alpha$ -P-UTP was chemically synthesised with the label in the  $\alpha$ -phosphorus atom. The figures are the mean results of two experiments, each performed in duplicate.

shows that the uptake of  $^{14}\text{C}$ -adenine by nuclear RNA is sensitive to the presence of TSH in the medium. Increasing levels of TSH resulted in stimulation of RNA incorporation which was roughly proportional to the logarithm of the dose added. Under similar conditions of incubation, uptake of  $^{14}\text{C}$ -adenine by the RNA of isolated liver cell nuclei was not responsive to TSH.

The increased incorporation of  $^{14}\text{C}$ -adenine into the RNA of thyroid slices after addition of TSH has also been observed by Hall<sup>9</sup>, who attributed this effect to more rapid formation of free nucleotides from the base. We therefore incubated thyroid nuclei with UTP labelled with phosphorus-32 in the  $\alpha$ -phosphorus atom; unlabelled ATP, GTP and CTP were also added in equimolar proportions to the medium. Table 2 shows that TSH induced the same increase in uptake of phosphorus-32 from UTP in the presence of the other nucleotide triphosphates as observed when  $^{14}\text{C}$ -adenine was incubated alone. It would thus appear that increased free nucleotide synthesis is not the factor responsible for the stimulant action of TSH on  $^{14}\text{C}$ -adenine uptake into nuclear RNA.

The suppression by puromycin of the action of TSH on RNA synthesis in thyroid slices (Table 1) suggests that the hormone may first affect synthesis of nuclear protein. Purified thyroid nuclei were therefore incubated with  $^{14}\text{C}$ -leucine. The same incubation medium was used, with 1  $\mu\text{C}$ .  $^{14}\text{C}$ -DL-leucine in place of the labelled adenine. At the end of incubation, the samples were treated as for RNA isolation, but the DNA-protein fraction was retained and dissolved in 0.3 N sodium hydroxide for counting and for protein determination<sup>10</sup>. The addition of TSH to the incubation medium had no significant effect on leucine incorporation into mixed nuclear proteins (Fig. 3), although the same dose increased uptake of  $^{14}\text{C}$ -adenine into nuclear RNA by 60 per cent (Fig. 2).

Fig. 2. Uptake of  $^{14}\text{C}$ -adenine by the RNA of thyroid cell nuclei during incubation of isolated nuclei with various concentrations of thyroid stimulating hormone. Each point is the mean result of two experiments.

Table 3. ADENINE UPTAKE BY RNA DURING INCUBATION OF ISOLATED THYROID NUCLEI WITH <sup>14</sup>C-ADENINE AND THYROID-STIMULATING HORMONE

Pre-incuba- tion with inhibitor (min)	Time of incubation (min)	Control nuclei			TSH-treated nuclei			Increase with TSH		
		No inhibitor	Puromycin	Actino- mycin D	No inhibitor	Puromycin	Actino- mycin D	No inhibitor	Puromycin	Actino- mycin D
None	10	400	400	370	890	840	530	+490	+440	+150
	20	1,030	1,240	780	2,900	1,540	1,900	+1,870	+800	+1,120
	30	1,670	1,440	960	3,400	1,650	2,330	+1,730	+210	+1,560
20	10	200	90	200	330	180	200	+130	+40	+25
	20	550	400	200	720	300	230	+170	0	+30

Puromycin (100 µg/ml. medium) and actinomycin D (10 µg/ml. medium) were added either at the time of addition of <sup>14</sup>C-adenine and thyroid stimulating hormone (0.1 I.U./ml.) or 20 min beforehand. Each entry is the mean result from two experiments and is expressed as counts/min/mg RNA.

This finding indicates that under our conditions TSH does not have a general effect on nuclear protein synthesis; however, this does not exclude an action of TSH limited to synthesis of one nuclear protein.

The actions of puromycin and actinomycin on RNA synthesis by isolated thyroid nuclei were investigated under two conditions of incubation. Either inhibitors were added along with <sup>14</sup>C-adenine and TSH, or else the nuclei were incubated with the inhibitors for 20 min before the addition of label and hormone. Table 3 shows that addition of puromycin along with <sup>14</sup>C-adenine did not affect incorporation into the RNA of the control nuclei at any time up to incubation for 30 min; nevertheless, it suppressed the effect of added TSH from 10 min incubation onwards. This confirms the conclusion drawn from the tissue slice experiments (Table 1) that the increased incorporation of <sup>14</sup>C-adenine caused by TSH addition requires preliminary synthesis of protein.

The addition of actinomycin to nuclei at the same time as addition of <sup>14</sup>C-adenine resulted in a depression of adenine uptake throughout incubation. Actinomycin also reduced the increased incorporation of adenine into nuclear RNA caused by addition of TSH, but only in proportion to its effect on adenine uptake by the RNA of the control nuclei. This indicates that actinomycin added to nuclei along with <sup>14</sup>C-adenine and TSH does not affect the synthesis of nuclear protein responsible for the enhancement of adenine uptake by RNA. This lack of effect of actinomycin could be due to a greater rate of penetration and action of TSH added at the same time as the inhibitor. Accordingly, thyroid nuclei were pre-incubated with puromycin or actinomycin for 20 min before the addition of TSH and <sup>14</sup>C-adenine. Table 2 shows that both inhibitors now completely suppressed

the action of TSH on adenine incorporation. These findings suggest that the first effect of TSH on nuclear RNA metabolism is actinomycin-sensitive and thus may involve synthesis of a messenger RNA for a specific nuclear protein. The synthesis of this protein can also be inhibited by puromycin, which interferes with the assembly of amino-acids on this mRNA template. Since this protein is necessary for the stimulant action of TSH on general RNA synthesis, it could be an RNA polymerase or polymerases. The proposed sequence of events following the action of TSH on thyroid nuclei is shown in Fig. 4.

Fig. 4. Diagram showing the mode of action of thyroid stimulating hormone on thyroid nuclear metabolism.

Many effects of TSH on thyroid cell metabolism have been described. These include actions on pyridine nucleotide concentrations<sup>11</sup>, glucose oxidation<sup>12</sup>, sodium uptake<sup>13</sup> and phospholipid turnover<sup>14</sup>, all of which occur within 10 min of adding TSH to thyroid slices. It is not possible at present to relate these reported early actions of TSH on whole cell preparations to the changes we have observed in isolated nuclei.

This work was supported by U.S. Public Health Service grant AM-0544 and grant CA-07087 from the U.S. National Cancer Institute. We thank Messrs. Merck, Sharp and Dohme, Inc., New York, for a gift of actinomycin D. Dr. R. M. S. Smellie kindly provided the sample of <sup>32</sup>P-UTP.

## INDICATIONS OF THE PRESENCE OF ORGANOCHLORINE INSECTICIDES IN RAINWATER IN CENTRAL ENGLAND

By G. A. WHEATLEY and J. A. HARDMAN

National Vegetable Research Station, Wellesbourne, Warwick

**A**LTHOUGH organochlorine insecticides have been widely used for many years, their exact fate in the environment is still largely unknown. Occasionally, background levels of dieldrin in untreated soil in microplots at Wellesbourne have appeared to increase by amounts too large to be explained solely by variations in sampling and analytical techniques. Appreciable amounts of insecticide are known to be 'lost', presumably into the atmosphere, during spraying operations<sup>1</sup>, and Harris and Lichtenstein considered it evident from their experiments "that volatilization of insecticidal residues from soil is a major factor in their 'disappearance'"<sup>2</sup>. In the spring of 1964, we decided to explore the possibility that insecticides might now be present in the atmosphere and consequently in rainwater at concentrations sufficient to account for apparent residue increases observed in the microplots.

An 8-in. diameter copper rain gauge was set up on short grass at the Agro-Meteorological Station at Wellesbourne on April 1, 1964, and rainwater was collected in a 2.5-l. glass bottle placed inside the body of the rain gauge. The collecting bottle was changed on May 1 and afterwards on the first day of each calendar month so that monthly rainfall samples were obtained during April 1964–February 1965 inclusive. Supplementary samples of rainwater were also collected on occasions during January and March 1965 after rain had begun and it was evident that a prolonged period of rain could be expected. Glass dishes were placed on a wire-mesh grid about 40 cm above the ground in the centre of a grass field at Wellesbourne and, when the rain stopped falling, the water collected in the dishes was emptied into a glass bottle and taken to the laboratory.

Throughout the work scrupulous attention was given to minimizing potential contamination or interference from reagents or other within-laboratory sources. The all-glass apparatus used was washed successively in hot water with detergent, distilled water, acetone and hexane and then heated for several hours at 100°–110° C. It was rinsed again with acetone and hexane prior to use and the purity of the final rinsings was tested by gas/liquid chromatography. Reagent blanks were also processed concurrently with the samples.

The method used to analyse the April–October monthly rainfall samples was of marginal sensitivity, but a simpler, more sensitive method was developed before the later samples were analysed. In the latter method, the rainwater was extracted with hexane and, by maintaining a ratio of 30 ml. hexane to 1 l. of water,  $\gamma$ -BHC, dieldrin and  $p,p'$ -DDT were found to be extracted with an efficiency in excess of 95 per cent. The hexane extract was passed through hexane-washed anhydrous sodium sulphate and concentrated under reduced pressure at 57° C to leave about 0.2 ml., which was subjected to thin-layer chromatography on 'Silica Gel G' (Merck), the adsorbent having first been washed by pre-developing the plates with acetone. The corresponding reagent blank extract and analytical grade specimens of  $\gamma$ -BHC, aldrin, dieldrin and  $p,p'$ -DDT were applied to the same thin-layer plate. After developing with a 4:1 mixture of hexane:benzene, the area occupied by the sample and reagent blank extracts was masked while the plate was being sprayed with silver nitrate/phenoxyethanol reagent before being exposed to ultra-violet light to reveal the reference spots. Adsorbent was removed from the chromatographic axes

of the sample and reagent blank extracts in  $R_f$  positions corresponding to those of  $\gamma$ -BHC, dieldrin and  $p,p'$ -DDT, and it was eluted with a 1:1 mixture of hexane:benzene to give 0.20 ml. extract.

Gas chromatograms of the extracts were obtained using a Shandon FB-4 ionization chromatograph fitted with an electron capture detector operated at 5 V. A stainless steel column, 2 mm internal diam. and 40 cm long, packed with 1.5 per cent w/w of a 6:4:1 mixture of 'E301' silicone elastomer: 'Apiezon L': 'Epikote 1001' resin on 100–120 mesh non-acid-washed 'Chromosorb G' was operated at 157° C with a nitrogen flow of 1.0 ml./s. The injection port temperature was approximately 220° C and 5  $\mu$ l. volumes were usually injected. The quantitative estimates were obtained by comparing the peak heights on the gas chromatograms of the extracts with those given by standards prepared from analytical grade specimens of the insecticides, deducting the value for the appropriate reagent blank and correcting for recovery of the insecticides from the thin-layer plates, found to be 90, 70 and 50 per cent for dieldrin,  $\gamma$ -BHC and  $p,p'$ -DDT, respectively.

All the rainwater samples examined so far have yielded solutes identical in behaviour to  $\gamma$ -BHC and dieldrin in both the thin-layer and gas/liquid chromatographic systems. With the more sensitive method used to analyse the post-October samples, a solute corresponding in behaviour to  $p,p'$ -DDT was also detected. The concentrations of the solutes in the rainwater samples varied from month to month and they appeared to be independent of the total monthly rainfall recorded in a nearby rain gauge. The quantitative results for the April–October and the November–February monthly samples and the direct collections made in January and March 1965 are summarized in Table 1.

Microchemical reactions adapted from those proposed by Hamence<sup>3</sup> were used in an attempt to confirm the identity of the extracted solutes in the post-October samples. None of the solutes was affected by chlorination. Treatment with alcoholic potash removed the apparent  $\gamma$ -BHC peaks from the chromatograms, eliminated the apparent DDT peaks and enhanced the response at the retention time of  $p,p'$ -DDE. It had no observable effect on the apparent dieldrin peaks. Bromination eliminated the apparent dieldrin peaks from the chromatograms, yielding several ill-defined peaks with long retention times. In these microchemical tests, the solutes from the rainwater were indistinguishable in behaviour from comparable nanogram amounts of analytical grade specimens of the insecticides.

An estimated 50 nanograms of apparent  $\gamma$ -BHC was obtained from a sample of rain collected on March 15, 1965, and a simple bioassay test using male *Drosophila*

Table 1. AVERAGE CONCENTRATIONS OF APPARENT ORGANOCHLORINE INSECTICIDES FOUND IN RAINWATER SAMPLES, EXPRESSED AS PARTS PER 10<sup>11</sup> PARTS OF RAINWATER

† Four samples.

indicated that, within the limitations of the test, the solute from the rainwater was as markedly toxic as analytical grade  $\gamma$ -BHC.

The results of this investigation suggest that the rainwater samples obtained at Wellesbourne contained detectable amounts of  $\gamma$ -BHC, dieldrin and DDT, but, unfortunately, infra-red spectrography could not be used to confirm the identity of the minute amounts of the solutes encountered. Nevertheless, it was clear that the apparent increases in residues in the untreated microplots could not be accounted for by fall-out of insecticide in rain because calculations showed that 1 part of solute in  $10^{12}$  parts of rainwater could deposit only 2.7 mg of solute per acre for a 24-in. annual rainfall. No significant increase in the contamination of agricultural land seems likely to arise from this source, but the presence of organochlorine insecticides in the atmosphere and in rain would aid their dispersion in the environment and might explain the occurrence of residues in unexpected places<sup>4</sup>.

In view of the world-wide use of organochlorine insecticides and the extensive distribution of their residues in soil, together with the foregoing evidence, it is possible that they might now contaminate the atmosphere continuously. We have estimated from data on their usage<sup>5</sup> and rates of loss from soil that residues of aldrin, dieldrin,  $\gamma$ -BHC and DDT amounting to about 1, 8, 2 and 30 tons,

respectively, are probably present in the upper 5 mm of soil of the total cropped acreage in England and Wales, even during the winter period when insecticides are not being extensively used. The emanation of vapours from such extensive superficial residues might give rise to a background level of contamination in the atmosphere to which would be added variable direct contributions from present pesticide applications on both local and possibly global scales.

The samples examined during this work were all collected in a locality in central England and, if the identification of organochlorine insecticides in rainwater is afterwards confirmed, rainwater samples will have to be analysed from many localities before the extent and variations in the degree of atmospheric contamination can be fully assessed.

## GROWTH OF TRANSPLANTED LEUKAEMIC CELLS IN THYMECTOMIZED MICE

By DR. DELPHINE M. V. PARROTT and DR JUNE EAST

Imperial Cancer Research Fund, London, N.W.7

IT is now clear that the immunological responses of mice thymectomized within 24 h of birth are selectively, not totally, impaired. Such animals may be unable to reject allogeneic skin grafts<sup>1</sup>, immunologically competent lymphoid cells from normal donors with different H2-histocompatibility loci<sup>2,3</sup> or tumour homografts<sup>4</sup>, but their capacity to produce humoral antibodies to certain antigens is unimpaired<sup>5</sup>. In the experiments described here allogeneic (AKR) leukaemic spleen cells were used in preference to skin grafts to test the immunological capabilities of C3H/B<sub>1</sub> mice thymectomized 12 h–25 days after birth. Leukaemic cells grow rapidly, disseminate widely and provoke both humoral antibody and cellular responses<sup>6</sup>. They might, therefore, be expected to stimulate the entire lymphoid system as compared with skin grafts which primarily elicit limited cellular reactions in the local lymph nodes. It is also more practicable to assess fine differences in immunological responsiveness by injecting varying numbers of leukaemic cells than to use multiple skin grafts provided by donors of several strains. Three parameters, age at thymectomy, age at injection and dose of leukaemic cells, were examined. In this investigation only the overall immune responses of the mice were assessed, no distinction being made between the cellular and humoral components.

Thymectomized or intact inbred C3H/B<sub>1</sub> mice were given  $1 \times 10^5$  or  $1 \times 10^6$  AKR leukaemic spleen cells subcutaneously in a volume of 0.1–0.2 ml. Groups of intact inbred AKR mice injected with  $1 \times 10^5$ ,  $1 \times 10^6$  or  $1 \times 10^7$  leukaemic cells were also included for comparison. Animals which did not die of leukaemia were killed for examination at least six weeks after injection. New-born C3H/B<sub>1</sub> mice were thymectomized using anaesthesia produced by cooling<sup>7</sup>, but ether was used for operations on weanlings aged 23–25 days. Wherever practicable, some mice in each litter were left intact. The leukaemic cells used were 117th–170th transplant generations of a lymphatic leukaemia which had originated spontaneously in an 11-month-old female AKR

mouse and had been passaged regularly, since November 1960, in young adult AKR recipients. The inocula were prepared from suspensions of spleen cells in Hanks's solution which were counted and diluted as required in the same medium.

**Response of intact mice to leukaemic cells** (Table 1). Intact AKR mice injected with leukaemic AKR spleen cells at 27–100 days died within 8–16 days. They showed hepatosplenomegaly, gross enlargement of all the lymph nodes and leukaemic infiltration of many other organs, including the thymus. Few tumours were seen at the site of inoculation and then only in mice which had received the smallest dose of one thousand cells. Survival time decreased as the number of leukaemic cells in the inoculum was increased from one thousand to one million, and young mice injected when 28 days old died more quickly than older animals aged 80–100 days.

By contrast, the majority of the intact C3H/B<sub>1</sub> mice rejected the allogeneic leukaemic cells and survived. Even nestlings aged 14–18 days were unaffected by a thousand cells. Some (7/34) animals, less than six weeks old, died of leukaemia when the cell dose was increased, but the older recipients (42–211 days) survived. It is not surprising that a few of the C3H/B<sub>1</sub> mice accepted the allogeneic leukaemic cells since they have the same histocompatibility locus (H2<sup>b</sup>) as the AKR strain.

\* Spleen suspensions from wasting mice passaged—see text.

† Additional dose of  $1 \times 10^6$  leukaemic cells given 47-51 days later.

*Response of thymectomized mice to leukaemic cells.* A number of factors determined the design of these experiments. For example, *C3H/Bi* mice thymectomized 12-48 h after birth develop a wasting syndrome and die prematurely, usually within 12 weeks<sup>2,3,4</sup>, and their immunological responses had, preferably, to be tested before they were six weeks old despite the fact that intact animals of this age were unable completely to resist large numbers of leukaemic cells. Wasting mice can be distinguished from leukaemic mice, *post mortem*, by the normal or small size of their lymphoid organs and, histologically, by a lymphocyte deficit in their tissues and blood, but subsidiary passage experiments were also introduced to check wasting mice for the presence of leukaemic cells. These restrictions did not apply to most mice thymectomized later than 48 h *post partum* because progressive delay in thymectomy minimizes and finally eliminates the wasting syndrome<sup>2,3,4</sup>.

Only 2/7 *C3H/Bi* mice thymectomized within 24 h of birth and none of the intact controls died of leukaemia when injected with one thousand allogeneic leukaemia cells at 35-38 days of age (Table 2). The remainder (5/7) died wasting at the same age (43-54 days) as uninjected thymectomized mice, on average 12.4 days after injection. It was possible that all the thymectomized mice would have afterwards become leukaemic if wasting had not intervened, but it was noted that they wasted at the same time after injection as intact *AKR* mice, given an identical dose of cells, succumbed to leukaemia, namely, 12.0 days. We assumed, therefore, that some of the *C3H/Bi* mice thymectomized on the day of birth had at least offered token resistance to the leukaemic cells.

This assumption was tested by giving the leukaemic inoculum at the much earlier age of 16-24 days (Table 2). In this case 4/8 mice thymectomized within 24 h of birth developed leukaemia 12-18 days after the injection of a thousand cells, but an equal number survived for as long as 21-32 days without becoming leukaemic and wasted at the same age as uninjected thymectomized mice. By delaying thymectomy until 24-48 h the incidence of leukaemia was reduced to nil although all the mice again wasted at the expected time (Table 2).

When wasting was ameliorated by further postponing thymectomy until 48-72 h after birth, none of the seven mice tested when 52-194 days old developed leukaemia. If, however, an additional and greater (one million) number of leukaemic cells was given to six of these animals after an interval of 47-51 days they were unable to make a secondary response and died rapidly of leukaemia 9-12 days later. Intact controls, similarly treated, showed no leukaemic symptoms (Table 2).

Immunological deficiencies in the thymectomized *C3H/Bi* mice became apparent when the number of leukaemic *AKR* cells in the test dose was increased to a million (Table 3). Many more mice (40/50) thymectomized to four days *post partum* died of leukaemia if tested 27-58 days than did intact animals (7/49) of a comparable age. Even mice thymectomized at 50-96 h, showed no wasting symptoms, still died precipi-

tately when the leukaemic inoculum was given as late as five months after the operation. If thymectomy was delayed until weaning, only 5/27 mice developed leukaemia.

Despite the large number of leukaemic cells injected, some of the animals thymectomized less than 24 h or 24-48 h after birth died wasting and were not overtly leukaemic (Table 3). It was evident that 4 of 18 mice thymectomized at 24-48 h wasted at the same time as, or later than, those which showed gross leukaemic infiltration. It seemed that these few mice had either managed to reject the malignant cells or to delay their growth.

*Passage experiments.* Cell suspensions were prepared from the spleens of thymectomized *C3H/Bi* mice which had received a thousand leukaemic cells at 14-16 or 16-24 days and which had been killed wasting but not overtly leukaemic 21-55 days later. These included four mice thymectomized 12-24 h after birth and three animals thymectomized 24-48 h *post partum* (Table 2). Healthy intact litter-mates, similarly treated, were killed at the same time to provide control material.

Concentrated spleen cell suspensions from each donor were then injected subcutaneously into groups of intact two-month-old *AKR* mice. None of the 46 recipients showed any gross or microscopic evidence of leukaemia when they were killed six weeks later, although similar recipients injected with spleen suspensions from three leukaemic thymectomized donors died within one week of passage.

Allogeneic leukaemic cells can be used to test the immunological capabilities of thymectomized mice. The test is stringent but it has the virtues of flexibility, precision and simplicity. The results obtained confirm our previous statements that any assessment of the immunological status of thymectomized mice must take into account the fact that they are capable of some lymphoid development and that their ability to make an immunological response may be determined by the nature and extent of the antigenic stimulus applied and the age at which it is given<sup>2,10</sup>.

The dose of leukaemic cells was the most important of the three parameters examined. If the test inoculum contained only a thousand allogeneic leukaemic spleen cells a considerable number of neonatally (12-72 h) thymectomized *C3H/Bi* mice, like intact controls, were able to marshal their immunological resources and reject

Table 3. RESPONSE OF THYMECTOMIZED *C3H/Bi* MICE TO  $1 \times 10^6$  *AKR* LEUKAEMIC SPLEEN CELLS INJECTED SUBCUTANEOUSLY

them. That rejection had occurred was suggested by the passage experiments which showed that no transplantable leukaemic cells were present in thymectomized wasting animals or in their intact litter-mates. When the test dose was small a slight delay in thymectomy of 12-48 h *post partum* enabled the animals to combat the leukaemic cells more effectively. Nevertheless, mice thymectomized 48-72 h after birth were unable to mount a secondary response against a more severe antigenic stimulus.

If the test dose was increased to a million leukaemic cells the majority of the animals, whether thymectomized at 12 h or at 4 days, were unable to react immunologically and died of leukaemia 8-16 days later. The mice even accepted and succumbed precipitately to cells injected 5 months after thymectomy. Only mice thymectomized at weaning and intact controls rejected this number of leukaemic cells and survived. One important fact revealed by the high dosage levels was that mice thymectomized at the comparatively late age of 4 days were immunologically impoverished. Yet such animals, under ordinary laboratory conditions, do not waste but grow normally and live their full life span. Thus, apparent normality may disguise a very real immunological defect.

We consider the ability of neonatally thymectomized C3H/B<sub>6</sub> mice to make a primary response to small numbers

of allogeneic leukaemic cells and their vulnerability to larger doses to be equally striking findings. While no attempt was made to differentiate between cellular and humoral responses to the injected cells, it is possible to speculate that the residual responses of thymectomized mice to small numbers of cells were mediated by cytotoxic antibody and the failure to respond, either primarily or amnestically, to large numbers of cells was due to defective cellular immune mechanisms. This hypothesis must await further experimentation but it must be concluded that an immunological system correctly established by the thymus in very early life is of considerable importance in combating the growth of transplanted malignant cells.

## STRUCTURE OF THE PIGMENTS OF PRECOOKED IRRADIATED MEATS

By Dr. BASIL G. TARLADGIS\* and A. M. F. EHTASHAN-UD-DIN

Department of Food Technology, University of New South Wales, Kensington, Sydney

IT has been known for some years that the brown colour of cooked meats is partially converted to red by ionizing radiations<sup>1</sup>. The red colour of pre-cooked irradiated meats has been characterized by Tappel as a denatured globin haemochrome<sup>2</sup>. However, Tappel's work was performed on meats which had received a radiation dose of  $2 \times 10^6$  rads only. Therefore, the character of the pigment in cooked meats treated with various radiation doses is still doubtful.

It has been previously shown that the colour of the iron-porphyrin co-ordination complexes responsible for the colour of meats treated in various ways depends not only on the oxidation state of the iron, but on the electronic configuration of the  $3d$  electrons of the metal ion<sup>3,4</sup>. In turn, the ligands occupying the  $3d$  orbital of the iron directly affect the electronic configuration of the iron<sup>5</sup>, and, thus, the colour of meat<sup>6</sup>. In the case of pre-cooked irradiated meats, both the ligands and the electronic configuration of the iron in the porphyrin co-ordination complex are unknown. In addition, very little can be found in the literature regarding the total cooked meat pigment losses which occur during radiation.

Recent reflectance investigations provided evidence on the electronic configuration of the iron-porphyrins responsible for the colour of cooked and cured meats<sup>7,8</sup>. It is thought that application of the same methods may throw more light in the structure of the pigments of irradiated cooked meats.

The purpose of the work recorded here was, therefore, to provide evidence regarding the identity of the pigments responsible for the colour of the irradiated cooked meats and to evaluate the pigment losses that occur during radiation.

Fresh beef, lamb, veal and pork were purchased at a local market, most of the fat was removed and the meat was minced in a mechanical mincer. After thorough mixing by hand, the meat was packed in No. 301 cans, 175 g of meat per can, sealed under vacuum and cooked

in a retort to an internal temperature of 70° C. Half the cans, packed in dry ice, were shipped to the Australian Atomic Energy Commission radiation facilities at Lucas Heights, New South Wales, where they received doses of ionizing radiation ranging from  $1 \times 10^4$ – $5 \times 10^6$  rads, using a cobalt-60 source. The remaining cans were stored in a freezer, at a temperature of -20° C, to serve as controls. The reflectance spectra of all samples were recorded, after separating the surface layer and mincing the meat again, using a Beckman DK2 recording spectrophotometer with the appropriate attachments, as described in previous publications<sup>9,10</sup>. The total pigment content of the various meats was extracted and estimated according to Hornsey's method<sup>6</sup>.

The reflectance spectra of the irradiated pre-cooked beef, lamb, veal and pork are shown in Figs. 1-4 respec-

Fig. 1. Reflectance spectra of cooked beef, after irradiation with the following doses (rads): 1, None; 2,  $1 \times 10^4$ ; 3,  $5 \times 10^4$ ; 4,  $2 \times 10^5$ ; 5,  $5 \times 10^6$ .

Fig. 2. Reflectance spectra of cooked lamb, after irradiation with the following doses (rads): 1, None; 2,  $1 \times 10^4$ ; 3,  $5 \times 10^4$ ; 4,  $2 \times 10^5$ ; 5,  $5 \times 10^5$ .

Fig. 3. Reflectance spectra of cooked veal, after irradiation with the following doses (rads): 1, None; 2,  $1 \times 10^4$ ; 3,  $5 \times 10^4$ ; 4,  $2 \times 10^5$ ; 5,  $5 \times 10^5$ .

tively. The spectra of the unirradiated controls are included for comparison.

In general, the reflectance spectra of the various cooked meats and at the same radiation dose-level are very similar. The observed slight differences are to be expected, due to variations in pigment content.

The intensity of all spectra increases with radiation, while the ratio of the reflectance maxima of  $a:b$  bands ( $580:540\text{ m}\mu$ ) rises also, tending to reach unity. At the same time, the maxima of both  $a$  and  $b$  bands shift to shorter wave-lengths with radiation, while those of the  $\gamma$ - (Soret,  $400\text{ m}\mu$ ) band move toward longer wave-lengths (Table 1). In addition, and at radiation doses above  $5 \times 10^4$  rads, the charge transfer bands at  $485$  and  $640\text{ m}\mu$  disappear.

Table 2 shows the total pigment content of the unirradiated controls and that after radiation at the various dose-levels. It is interesting that during radiation at

Table 2. TOTAL PIGMENT IN P.P.M. OF HAEMATEX

	Beef	Lamb	Veal	Pork
Non-irradiated	209	202	98	74
Irradiated (rads):				
$1 \times 10^4$	166	162	75	55
$5 \times 10^4$	166	155	75	54
$2 \times 10^5$	154	143	68	50
$5 \times 10^5$	132	127	61	46

least 50 per cent of the total pigment loss occurs at a dose of  $100,000$  rads.

The reported spectra in Figs. 1-4 and values in Tables 1 and 2 represent averages obtained after several measurements on at least 4 different samples from each treatment.

In interpreting the spectra of irradiated cooked meats, one is faced with the inconsistency that the intensity of the spectra is inversely proportional to the total pigment content of the meat. However, it is well known that the absorption or reflectance spectra of the metal co-ordination compounds arise from electronic transitions initiated by absorption of light<sup>7</sup>. It is equally known that the intensity of a spectrum depends solely on the spin state of the metal ion of the co-ordination complex<sup>8,9</sup>; for example, equal amounts of met-, oxy- and haemo-globin possess much different  $E_{\text{max}}$ <sup>10</sup>. The differences are explained because the  $d-d'$  electronic transition of the high-spin methaemoglobin is a forbidden one, in the low-spin oxyhaemoglobin is a partially allowed one, while in the high-spin haemoglobin is an intermediate of those two<sup>7</sup>.

Close examination of the reflectance spectra of the irradiated cooked meats leads to the conclusion that both the spin and the valency state of the iron is affected by ionizing radiations. The increased intensity of the spectra, accompanied by the appearance of two distinct bands ( $a$  and  $b$  bands), clearly indicates that the high-spin ferri-porphyrin compound of the cooked meats is gradually converted by radiation to the low-spin state<sup>8</sup>.

It is further shown by the spectra that the reflectance maxima of both  $a$  and  $b$  bands shift to shorter wave-lengths with radiation, while those of the  $\gamma$ -band move toward longer wave-lengths. This is interpreted as strong evidence that the ferric ion of the metmyochromogen is gradually reduced by radiation to the ferrous form<sup>8,9</sup>. However, the reduction of the iron does not seem to be quantitative, since even at  $5 \times 10^5$  rads the intensity of the  $a$  band tends to be equal to but not higher than that of the  $b$  band. A complete reduction is indicated by an intensity  $a:b$  band ratio much higher than unity<sup>8</sup>.
